<p>(54) Title: PRODUCTION OF INSULIN-LIKE GROWTH FACTOR-1 IN METHYLOTROPHIC YEAST CELLS (57) Abstract Insulin-like growth factor-1 (IGF-1), a naturally occurring, relatively short, single chain polypeptide, is prepared by grow- ing methylotrophic yeast transformants containing in their genome at least one copy of DNA encoding IGF-1, in operational lin- kage with DNA encoding a signal sequence, which is effective for directing secretion of proteins from the host cells and which also includes the proteolytic processing syte lys-arg and may include one or more glu-ala sequences. In preferred embodiments the signal sequence is the <i>S. cerevisiae</i> alpha mating factor pre-pro sequence. Expression of both the DNA encoding IGF-1 and the pre-pro signal sequence are regulated by a promoter region derived from a methanol responsive gene of a methylotrophic yeast. DNA constructs and recombinant methylotrophic yeast strains used for the expression and secretion of IGF-1 are also pro- vided. For preferred embodiments, protease deficient <i>Pichia pastoris</i> strains are provided.</p>

**PRODUCTION OF INSULIN-LIKE GROWTH
FACTOR-1 IN METHYLOTROPHIC YEAST CELLS**

RELATED APPLICATIONS

5 This application is a continuation-in-part of U.S.
Application Serial No. 07/578,728, to Brierley et al.,
filed September 4, 1990, "PRODUCTION OF INSULIN-LIKE
GROWTH FACTOR-1 IN METHYLOTROPHIC YEAST CELLS". The
subject matter of this application is also related to
10 U.S. Application Serial No. 07/678,916, to Gleeson et al.,
filed April 1, 1991, "GENES WHICH INFLUENCE PICHIA
PASTORIS PROTEOLYTIC ACTIVITY, AND USES THEREFOR". U.S.
Application Serial Nos. 07/578,728 and 07/678,916 are
incorporated herein in their entirety by reference
15 thereto.

FIELD OF THE INVENTION

The invention described herein relates to processes
for producing authentically folded biologically active
insulin-like growth factor-1 (IGF-1) using methylotrophic
20 yeast host cells, such as Pichia pastoris (P. pastoris).
The invention further relates to the methylotrophic yeast
that produce IGF-1, to DNA fragments for preparing
expression vectors that include DNA encoding IGF-1 and
that are used for transforming the methylotrophic yeast
25 cells, to the expression vectors, and to cultures
containing the transformed yeast cells.

BACKGROUND OF THE INVENTION

Insulin-like growth factor-1 belongs to a
heterogeneous family of peptides which share some of the
30 biological and chemical properties of insulin, but which
are antigenically distinct from insulin. Currently
available experimental evidence suggests that IGF-1
promotes growth by mediating the effects of growth
hormone. Thus, such processes as skeletal growth, cell
35 replicati n and oth r growth related pr cesses are

-2-

affected by IGF-1 levels. Physiological concentrations of IGF-1 have been shown to be influenced by such conditions as thyroid disease, diabetes and malnutrition (see Preece (1983) Horm. Blood, 4: 108). IGF-1 has also
5 been shown to act synergistically with other growth factors, for example, in accelerating the healing of soft and mesenchymal tissue wounds (see Lynch et al. (1989) J. Clin. Periodontol., 16: 545; and Lynch et al. (1987) Proc. Natl. Acad. Sci. USA, 84: 7696), and in enhancing
10 the growth of mammalian cells in serum-free tissue culture medium (see Burleigh et al. (1986) American Biotech. Lab., 4: 48).

Considering the many clinical and research applications of IGF-1, a ready supply of IGF-1 would be
15 of great value to the medical and biotechnology fields. Since isolation from natural sources is technically difficult, expensive, and time consuming, recent efforts have centered on the development of efficient recombinant methods for the production of IGF-1.

20 Among host cells that have been used for the production of heterologous proteins, E. coli and Saccharomyces cerevisiae (Baker's yeast) are probably the best characterized. Insulin-like growth factor-1 (IGF-1), which is a polypeptide of 70 amino acids with a
25 molecular weight of 7648 daltons, is a single chain protein that has three intrachain disulfide bridges. These disulfide bonds, along with numerous hydrogen bonds and hydrophilic interactions, maintain the compact tertiary structure of this molecule. E. coli, however,
30 does not possess the ability to produce disulfide bonds in proteins, so that proteins, such as IGF-1, that include disulfide bonds, when cloned into and expressed in E. coli, frequently are not stable and tend to aggregate into inactive complexes. In addition, IGF-1
35 produced in E. coli has to be extracted and treated with

-3-

oxidizing agents to produce the disulfide bonds. Upon reduction and reoxidation, IGF-1 refolds in a variety of ways, forming as many as 15 monomeric configurations (Meng et al. (1988) J. Chrom., 443: 183) because cell
5 breakage and too rapid formation of disulfide linkages results in random disulfide bond formation. In order to produce biologically active IGF-1, the resulting mixture of 15 different forms of IGF-1 must be separated. Consequently, the yield of purified product is very low
10 (Grossgian (1985) Gene, 18: 199).

Furthermore, since E. coli is a prokaryote, in order to produce IGF-1 molecules which contain the authentic N-terminal glycine, and not the initiating methionine present on the primary translation product, it is
15 necessary to express IGF-1 in E. coli as a fusion protein. Cleavage of mature IGF-1 from the initially produced fusion protein necessitates an additional step in the production process. Consequently, attempts to produce this peptide by recombinant means in E. coli host
20 expression systems results in a complex mixture of product forms which must be separated for further use (see, Grossgian (1985) Gene, 18: 199).

Eukaryotic host cells, including yeast cells, thus, are the host cells of choice for the expression of many
25 eukaryotic proteins. Yeast host cells offer clear advantages over bacteria in the production of heterologous proteins, including their ability to properly process pre-pro-heterologous proteins and secrete heterologous proteins into the culture medium.
30 Secretion of proteins from cells is often superior to production of proteins in the cytoplasm because secreted products are obtained in a higher degree of initial purity and further purification of the secreted products is made easier by the absence of cellular debris. In
35 addition, the secretory pathway of the cell and the

-4-

extracellular medium tend to be oxidizing environments which support disulfide bond formation necessary for proper folding of many proteins (Smith, et al. (1985) Science 229: 1219); whereas, the cytoplasm is a reducing environment in which disulfide bonds do not form. Thus, for production of sulfhydryl-rich proteins that rely on disulfide bonds to maintain the correct tertiary structures, there is a compelling need to develop eukaryotic hosts capable of secreting such proteins into the culture medium. Therefore, production of sulfhydryl-rich proteins, such as IGF-1, that contain appropriately formed disulfide bonds, can best be achieved by transit through the secretory pathway.

IGF-1 has been cloned into and expressed using S. cerevisiae host cells by introducing DNA encoding IGF-1 on autonomously replicating extrachromosomal elements. Gellerfors et al. ((1989) J. Biol. Chem., 264: 11444-11449) describes the production of IGF-1 in S. cerevisiae under the control of the S. cerevisiae actin promoter. The IGF-1 product is encoded by autonomously replicating plasmid-borne DNA. In a similar study, Bayne et al. ((1988) Gene 66: 235-244) describes the production of IGF-1 in S. cerevisiae under the control of the S. cerevisiae alpha mating factor promoter. The latter, however, reports yields of IGF-1 of only about 2 mg of IGF-1 per liter of fermentation broth.

In view of this low yield and the problems generally encountered with up-scaling the production of heterologous proteins in autonomous plasmid-based yeast systems, such as loss of selection for plasmid maintenance and problems concerning plasmid distribution, copy number and stability in fermentors operated at high cell density, there is a need to develop more efficient means for producing large quantities of biologically active IGF-1.

-5-

Therefore, it is an object of this invention to provide host cells and expression vectors that stably express IGF-1 and that secrete high concentrations of biologically active IGF-1.

5 It is another object of this invention to provide an expression system for the production of biologically active IGF-1 that, not only secretes high concentrations of biologically active IGF-1, but that can be readily scaled up to produce large quantities of such IGF-1.

10 SUMMARY OF THE INVENTION

Expression systems and method using the expression systems for the production of biologically active insulin-like growth factor-1 (IGF-1) using methylotrophic yeast host cells are provided. The methods of production
15 are readily scaled up from shake-flask cultures to large scale fermentors with no loss in IGF-1 productivity and without the need for making major changes in the fermentation conditions used for the growth of the transformed strains. Methods for isolation and
20 purification of the IGF-1 product are also provided.

The expression systems and methods provided herein avoid the problems encountered with heterologous protein expression in S. cerevisiae in which high level expression can only be achieved by the introduction of
25 multicopy plasmids into the host cells.

The expression system described herein uses methylotrophic yeast host cells, such as for example, P. pastoris, for the expression of IGF-1. Key features of the system include the ability to stably integrate and
30 express multiple copies of the DNA encoding IGF-1 and the DNA encoding the signals that direct secretion and processing of the IGF-1 and the ability to properly process mature IGF-1 from the expressed precursor form IGF-1 and to secrete the resulting mature IGF-1 product.
35 Another feature of the system resides in selection

-6-

of the promoter that has been used to control expression of the DNA encoding IGF-1. The promoter, which is derived from a methanol-responsive gene, such as AOX1, of a methylotrophic yeast, is tightly regulated and provides
5 for high-level regulated expression of genes placed under its control (see, e.g., European Patent Application No. 85113737.2, published June 4, 1986, under No. 0 183 071, now issued in the United States as U.S. Patent No. 4,855,231).

10 Expression and secretion of high levels of IGF-1 peptide has been accomplished by transforming a methylotrophic yeast host with a DNA construct that contains at least one copy, but may contain as many as six or more copies, of DNA encoding an IGF-1 peptide in
15 which the DNA is operably linked with DNA encoding a signal sequence that is effective for directing the processing and secretion of the IGF-1 peptide product. The DNA construct also includes a promoter region, which directs expression of the DNA encoding the signal
20 sequence and IGF-1 peptide, and a transcription terminator functional in a methylotrophic yeast.

The DNA construct provided here, also includes sequences of nucleotides that have sufficient homology with a target gene in the methylotrophic yeast host cell
25 genome, to effect stable integration. Integration takes place by addition or replacement at the site of the target gene. Alternatively, the DNA construct may be part of a circular plasmid, which will integrate by addition at a site of homology between the host and the
30 plasmid sequence.

In accordance with other embodiments, expression vector containing the DNA construct which includes at least one copy of an expression cassette are provided. hereinabove.

35 According to another aspect, there are provided

-7-

novel methylotrophic yeast cells containing in their genome at least one copy of the above-described DNA fragment. In preferred embodiments the cells are deficient in one or more proteases that are not essential for proper cleavage of the precursor form of IGF-1.

In preferred embodiments, the host cell is P. pastoris, the promoter is the AOX1 promoter, and the signal sequence is the S. cerevisiae alpha-mating factor (α MF) pre-pro sequence, which includes a processing sequence of the formula lys-arg-(glu-ala)_x in which x is preferably between 0 and 3. Methylotrophic yeast cells in which at least one copy of this DNA construct has been introduced efficiently produce and secrete biologically active IGF-1 peptides into the medium. In preferred embodiments, IGF-1 has been very efficiently produced in, and secreted from the methylotrophic yeast P. pastoris.

The polypeptide product produced by the methylotrophic host cells, is secreted into the culture medium at high concentrations; the level of IGF-1 peptides secretion is many times the concentrations that are reported for the secretion of IGF-1 from S. cerevisiae (see, e.g., Bayne et al. (1988) Gene, 66: 235-244). IGF-1 peptides are produced by methylotrophic yeast cells that contain in their genome one or more copies of a DNA sequence operably encoding IGF-1 peptides operably linked with DNA encoding a signal sequence, such as the S. cerevisiae α -mating factor (α MF) pre-pro sequence, which includes at least one site, such as lys-arg, that is sufficient for proper proteolytic cleavage of mature IGF-1 from the pre-pro-protein, under the regulation of a promoter region of a methanol-responsive gene of a methylotrophic yeast. In addition, the DNA encoding the signal sequence may encode one or more glu-ala sequences, which also serve to direct processing. The number of glu-ala sequences is

-8-

preferably from 0 to 3, but may include more copies. The number of copies is limited by the ability of the selected host to properly process the pre-pro-protein.

According to a still further embodiment, there is provided a process for producing IGF-1 peptides by growing methylotrophic yeast transformants containing in their genome at least one copy of a DNA sequence operably encoding an IGF-1 peptide, operably associated with DNA encoding the S. cerevisiae α MF pre-pro sequence. This pre-pro sequence includes a processing sequence lys-arg and may also include from 0 to 3 glu-ala spacer segments. Transcription of both the DNA encoding the signal and the DNA encoding the IGF-1 peptide is under the regulation of a promoter region of a methanol-responsive gene of a methylotrophic yeast. Under conditions that induce the promoter transcription of the DNA is induced resulting in expression and processing of the precursor IGF-1 and secretion of IGF-1 peptides into the culture medium.

Cultures of viable methylotrophic yeast cells capable of producing IGF-1 peptides are also within the scope of the present invention. In preferred embodiments, the yeast host cells that express and secrete IGF-1 have been modified by disruption of one or more host cell genes that directly or indirectly influence host cell protease expression. This disruption results in a reduction of some protease activities of the host cell, for example, proteinase A and carboxypeptidase Y activities.

A preferred process for recovering and purifying IGF-1 peptides from P. pastoris fermentation broth is described in U.S. Patent Application Serial No. 07/641,430. The preferred form of IGF-1 is a polypeptide product which exhibits substantially the same biological activities as natural insulin-like growth factor-1, as measured in recognized bioassays (see, e.g.,

-9-

Takano *et al.* (1976) *Acta Endocr.* 82: 449-459; Schoenie *et al.* (1982) *Nature* 296: 252-253; Copeland *et al.* (1983) *Am. J. Primatology* 5: 161-169 and Buul-Offers *et al.* (1986) *Ped. Res.* 20: 825-827) having substantially the same amino acid sequence as native IGF-1, Sequence ID No. 1, in the sequence listings. It is understood that polypeptides having some variation in amino acid sequences such as lacking one or more amino acids, or containing additional amino acids, or having some substituted amino acids are within scope of the invention, provided that these peptides exhibit the functional activity of IGF-1 according to known bioassays. Such IGF-1 may include, not only authentically folded IGF-1, but also the misfolded and multimeric forms of IGF-1 that exhibit the ability to detectably bind to IGF-1 receptors and that demonstrate at least one bioactivity associated with IGF-1. In addition, biologically inactive forms may be converted to active forms by reduction and oxidation.

DETAILED DESCRIPTION OF THE INVENTION

Definitions:

30 Unless defined otherwise, all technical and scientific terms used herein have the same meaning as is commonly understood by one of skill in the art to which this invention belongs. All publications mentioned herein are incorporated by reference theret. All U.S.
35 patents mentioned herein are incorporated in their

-10-

entirety by reference thereto.

As used herein, IGF-1 or an IGF-1 peptide is intended to include all the allelic variations of IGF-1. Moreover derivatives obtained by simple modification of the amino acid sequence of the naturally occurring product, such as by way of site-directed mutagenesis or other standard procedures, are included within the scope of the present invention. Forms of IGF-1 that exhibit similar biological activities to naturally occurring IGF-1 are also encompassed by the present invention. IGF-1 is intended to encompass all forms of IGF-1 present in the culture medium. Such IGF-1 may be mixture of several different three-dimensional forms. In addition to authentic IGF-1, which is the intact, the monomeric, correctly folded material, other forms may be present in the extracellular medium of the host cells that express IGF-1, such as misfolded proteins, multimeric forms such as dimers, and trimers. It is intended that the IGF-1 peptide, as used herein, includes any peptide that has the ability to bind to IGF-1 receptors and that exhibits at least one activity, such as the ability to promote cell proliferation or cell growth in a standard activity assay, that is associated with the biological activity of IGF-1 (see, e.g., Takano et al. (1976) Acta Endocr. 82: 449-459; Schoenie et al. (1982) Nature 296: 252-253; Copeland et al. (1983) Am. J. Primatology 5: 161-169 and Buul-Offers et al. (1986) Ped.Res. 20: 825-827).

As used herein, an IGF-1 peptide that has biological activity is a peptide that specifically binds to IGF-1 receptors, as detected by a standard assay, and that exhibits a biological activity associated with IGF-1 as measured in a recognized assay. Such assays are known to those of skill in this art.

As used herein, authentic IGF-1 refers to IGF-1 that includes disulfide bonds as they exist in naturally-

-11-

occurring IGF-1. Authentic IGF-1 may be efficiently recovered and purified from P. pastoris fermentation broth.

As used herein, mature IGF-1 refers to processed IGF-1 from which the signal and processing sequences have been cleaved. Mature IGF-1 includes authentic IGF-1 and any other forms of processed IGF-1 that are secreted into the medium. IGF-1 is intended to encompass peptides that have the ability to bind to IGF-1 receptors and to promote cell growth or proliferation as measured by any means known to those of skill in the art.

As used herein, pre-pro-IGF-1 refers to a polypeptide that includes a leader or signal sequence that effects secretion of mature IGF-1 into the extracellular space of said host and one or more processing signals that direct processing of the pre-pro-IGF-1 to produce the mature IGF-1. As used herein, secreted IGF-1 refers to processed IGF-1 that does not include the signal or leader sequence. Processed IGF-1 or processed protein refer to IGF-1 or protein from which the leader signal has been cleaved.

As used herein, a signal or leader sequence, which expressions are used interchangeably, refers to a sequence of amino acids that effects transport of a linked polypeptide through the cell membrane. A signal sequence refers to a sequence of hydrophobic amino acids at the amino terminus of the protein to which it is linked. DNA encoding a signal sequence is located downstream (3' in the direction of transcription) from the ATG start codon and upstream (5') from the DNA that encodes the structural gene. In addition, the signal sequence includes one or more sequence of amino acids, that are recognized by one or more host cell proteases, processing sites, interspersed between the signal sequence and the protein, whereby removal of the signal may be

-12-

effected. The signal sequence, processing sites and protein are referred to as a pre-pro-protein.

The signal sequences and processing sites contemplated for use herein are those that effect
5 transport of IGF-1 through the cellular membrane of a methylotrophic yeast host cell, such as P. pastoris. In preferred embodiments the signal sequence and processing sites, lys-arg and (glu-ala)_x, in which x is an integer, preferably between 0 and 3, are derived from the S.
10 cerevisiae α MF gene. Any signal sequence and processing sites that are effective for secreting mature IGF-1 into the extracellular space of a methylotrophic host known to those of skill in the art may be used. In preferred
15 embodiments, the signal sequences are selected so that fermentation cultures of methylotrophic host cells that have a cell density of about 300 g/L MeOH and that secrete at least about 10 mg/ml of authentic IGF-1 into the broth. DNA constructs encoding suitable signal
20 sequences and processing sites linked to DNA encoding IGF-1 may be prepared and introduced into the genome of a methylotrophic host by methods known to those of skill in the art or described herein and tested for their ability to direct secretion of mature IGF-1 into the medium. Any
25 signal sequence that leads to secretion relatively high concentrations, preferably more than 10mg/ml of mature IGF-1, is contemplated for use herein.

As used herein, heterologous DNA includes DNA that does not occur naturally as part of the genome in which it is present or which is found in a location or
30 locations in the genome that differs from that in which it occurs in nature. Heterologous DNA is generally not endogenous to the cell into which it is introduced, but has been obtained from another cell. Generally, although not necessarily, such DNA encodes RNA and proteins that
35 are not normally produced by the cell in which it is

-13-

expressed. Heterologous DNA may also be referred to as foreign DNA. Any DNA that one of skill in the art would recognize or consider as heterologous or foreign to the cell in which is expressed is herein encompassed by
5 heterologous DNA. Examples of heterologous DNA include, but are not limited to, DNA that encodes IGF-1, transcriptional and translational regulatory sequences, selectable or traceable marker proteins, such as a protein that confers drug resistance.

10 As used herein expression cassette refers to a DNA construct that includes sequences functional for both the expression and the secretion of IGF-1. Accordingly an expression cassette includes DNA encoding a promoter region, DNA encoding a transcription terminator region,
15 sequences sufficient for translation, secretion and proper processing of the expressed peptide. In addition, in preferred embodiments the expression cassette includes sequences at 5' and 3' ends that are derived from target locus in the host cell genome, whereby, upon introduction
20 into the host cell, the expression cassette is stably integrated into the host cell genome.

As used herein, the term DNA construct embraces expression cassettes and also includes DNA fragments that include more than one expression cassette.

25 As used herein, the term operative linkage or operably associated refers to relationship among elements of a DNA construct in which elements are arranged such regulatory sequences of nucleotides that are part of the construct directly or indirectly control expression of
30 DNA in the construct that includes protein- or peptide-encoding sequences of nucleotides.

As used herein, the term "a DNA fragment operably encoding IGF-1 peptides" includes DNA fragments encoding IGF-1 or any other "IGF-1 peptide" as defined
35 hereinabove. DNA encoding IGF-1 is known in the art and

-14-

may be obtained by chemical synthesis or by transcription of messenger RNA (mRNA) corresponding to IGF-1 into complementary DNA (cDNA) and converting the latter into a double stranded cDNA. Chemical synthesis of a gene for human IGF-1 is, for example, disclosed by Niwa *et al.* (1986) Annals of the NY Academy of Science, 469: 31-52, and Buell *et al.* (1985) Nucleic Acids Research, 13: 1923-1938. The requisite DNA sequence can also be removed, for example, by restriction enzyme digest of known vectors harboring the IGF-1 gene. Examples of such vectors and the means for their preparation are well known to those of skill in the art. See, *e.g.*, Niwa *et al.* (1986) Annals of the NY Academy of Science, 469: 31-52, and Buell *et al.* (1985) Nucleic Acids Research, 13: 1923-1938. The nucleotide sequence of a presently preferred IGF-1 gene used in accordance with the present invention is illustrated in FIG. 1 and is further elucidated in the examples.

As used herein, the term expression vector is intended to include vectors capable of expressing DNA that are in operational association with other sequences capable of effecting their expression such as promoter sequences in a selected host cell. In general, expression vectors usually used in recombinant DNA technology are often in the form of "plasmids", which are circular, double-stranded DNA loops, extrachromosomal elements. As used herein, the terms "vector" and "plasmid" are used interchangeably and are not intended to be limited, but to include any expression vectors or means that permits heterologous DNA to be expressed in a particular host cell.

As used herein, the term "culture" means a propagation of cells in a medium conducive to their growth, and all sub-cultures thereof. The term "subculture" refers to a culture of cells grown from

-15-

cells of another culture (source culture), or any subculture of the source culture, regardless of the number of times subculturing has been performed between the subculture of interest and the source culture.

- 5 The amino acids which occur in the various sequences of amino acid set forth in the specification have their usual, three- and one-letter abbreviations, routinely used in the art:

	<u>Amino Acid</u>	<u>Abbreviation</u>	
10	L-Alanine	Ala	A
	L-Arginine	Arg	R
	L-Asparagine	Asn	N
	L-Aspartic acid	Asp	D
	L-Cysteine	Cys	C
15	L-Glutamine	Gln	Q
	L-Glutamic Acid	Glu	E
	L-Glycine	Gly	G
	L-Histidine	His	H
	L-Isoleucine	Ile	I
20	L-Leucine	Leu	L
	L-Lysine	Lys	K
	L-Methionine	Met	M
	L-Phenylalanine	Phe	F
	L-Proline	Pro	P
25	L-Serine	Ser	S
	L-Threonine	Thr	T
	L-Tryptophan	Trp	W
	L-Tyrosine	Tyr	Y
30	L-Valine	Val	V

Host cells.

- Yeast species contemplated for use in the practice of the present invention are methylotrophs, that is species which are able to grow on methanol as carbon
- 35 sources. Species which have the biochemical pathways necessary for methanol utilization fall into four genera, Candida, Hansenula, Pichia, and Torulopsis. Of these, a substantial amount is known about the molecular biology of members of the species Hansenula polymorpha and Pichia
- 40 pastoris.

P. pastoris is the presently preferred yeast species. P. pastoris is a known industrial yeast strain

-16-

that is capable of efficiently utilizing methanol as the sole carbon and energy source.

DNA constructs.

The DNA constructs or expression cassette used for transforming methylotrophic yeast cells contain a methanol-responsive promoter from a methylotrophic yeast gene, DNA encoding IGF-1- (IGF-1 gene), a encoding a signal sequence in-reading frame with the gene, and and a transcription terminator functional in a methylotrophic yeast. The signal sequence may be any such sequence that functions to direct the secretion from and proper processing of IGF-1 in the yeast host cell. The *S. cerevisiae* α MF pre-pro sequence is the preferred signal sequence. The α MF pre-pro sequence includes a DNA sequence encoding a processing sequence lys-arg, and (glu-ala)_x spacer sequences wherein X is 0, 1, 2 or 3.

The *S. cerevisiae* alpha-mating factor is a 13-residue peptide, secreted by cells of the "alpha" mating type, that acts on cells of the opposite "a" mating type to promote efficient conjugation between the two cell types and thereby formation of "a-alpha" diploid cells (Thorner et al. (1981) The Molecular Biology the Yeast *Saccharomyces*, Cold Spring Harbor Laboratory, Cold Spring Harbor, NY, 143). The α -factor is synthesized as a 165 amino acid long precursor that contains an 83 residue leader and four α -factor peptide regions. Each region is preceded by a short spacer peptides of sequences:lys-arg-glu-ala-asp-ala-glu-ala; lys-arg-(glu-ala)₃ or lys-arg-(glu-ala)₂. The leader and spacer includes the amino acid sequences for proteolytic processing and secretion (see, e.g., Brake et al., Proc. Natl. Acad. Sci. USA, 81: 4642 (1984)).

There are a number of methanol-responsive genes in methylotrophic yeast. The expression of each is controlled by methanol-responsive regulatory regions,

-17-

also referred to as promoters. Any of such methanol-responsive promoters are suitable for use in the DNA constructs. Examples of specific regulatory regions include, but are not limited to, the promoter for the
5 primary alcohol oxidase gene from *Pichia pastoris* AOX1, the promoter for the secondary alcohol oxidase gene from *P. pastoris* AOX2, the promoter for the dihydroxyacetone synthase gene (DAS) from *P. pastoris*, the promoter for the P40 gene from *P. pastoris* the promoter for the
10 catalase gene from *P. pastoris*. Selection of suitable promoter regions and other regulatory regions is, in light of this disclosure, within the level of skill in the art.

The presently preferred promoter region employed to
15 drive IGF-1 gene expression is derived from a methanol-regulated alcohol oxidase gene of *P. pastoris*. *P. pastoris* is known to contain two functional alcohol oxidase genes: alcohol oxidase I (AOX1) and alcohol oxidase II (AOX2) genes. The coding portions of the two
20 AOX genes are closely homologous at both the DNA and the predicted amino acid sequence levels and share common restriction sites. The proteins expressed from the two genes have similar enzymatic properties but the promoter of the AOX1 gene is more efficient and provides for
25 higher levels of gene expression; therefore, its use is preferred for IGF-1 expression. The AOX1 gene, including its promoter, has been isolated and thoroughly characterized; see Ellis et al. (1985) Mol. Cell. Biol. 5: 1111 and U.S. Patent No. 4,855,231.

30 The DNA construct that is introduced into methylotrophic yeast cells contains, in addition to a methanol-responsive promoter of a methylotrophic yeast gene and DNA encoding IGF-1-, and DNA encoding an in-reading frame signal and processing sequence, contains a
35 transcription terminator functional in a methylotrophic

-18-

yeast. The transcription terminator functional in a methylotrophic yeast used herein has either (a) a subsegment which encodes a polyadenylation signal and polyadenylation site in the transcript, and/or (b) a subsegment which provides a transcription termination signal for transcription from the promoter used in the expression cassette. The entire transcription terminator is taken from a protein-encoding gene, which may be the same or different from the gene which is the source of the promoter.

The DNA construct may also contain a selectable marker gene. For this purpose, any selectable marker gene functional in methylotrophic yeast may be employed, including, but not limited to, any gene which confers a selectable phenotype upon methylotrophic yeast permitting such yeast cells to be identified and selectively grown from among a vast majority of untransformed cells. Appropriate selectable marker systems, for example, would be an auxotrophic mutant P. pastoris host strain and a wild type biosynthetic gene which complements the host's defect. For example, the S. cerevisiae or P. pastoris HIS4 gene may be used to complement His4⁻ P. pastoris strains, or the S. cerevisiae ARG4 gene or the P. pastoris ARG4 gene may be employed to complement Arg4⁻ mutants.

In addition, the DNA constructs may additionally include selectable marker genes which are functional in bacteria. Thus, any gene can be used which confers a phenotype on bacteria that allows transformed bacterial cells to be identified and selectively grown from among a vast majority of untransformed cells. This additional selectable marker permits such DNA to be introduced into and amplified in bacterial host cells, such as E. coli. Suitable selectable marker genes include the ampicillin resistance gene (Amp^r), tetracycline resistance gene

-19-

(Tc^r), and the like.

The DNA construct may include sequences allowing for replication and selection in bacteria, especially E. coli. In particular, the DNA construct may be inserted
5 into a plasmid or it may be circularized to form a plasmid that includes sequences for replication and extrachromal maintenance in bacteria. In this way, large quantities of the DNA fragment can be produced by replication in bacteria. When such amplification is
10 desired, the DNA construct should include bacterial origin of replication, to ensure the maintenance of the DNA construct from generation to generation of the bacteria. Exemplary bacterial origins of replication include the fl-ori, colisin, col E1, and others that are
15 known to or that can be identified by those of skill in the art.

The DNA construct may include multiple copies of the DNA encoding IGF-1 operatively linked to the signal and processing signals, and other transcriptional regulatory
20 signals, i.e., the DNA construct may include multiple copies of the expression cassette.

Transformation of methylotrophic yeast host cells with the DNA constructs.

Methods for transforming methylotrophic yeast, such
25 as, for example, P. pastoris, as well as methods for culturing methylotrophic yeast cells containing in their genome a gene encoding a heterologous protein, are generally known in the art. The expression cassettes may be introduced into the methylotrophic yeast cells by any
30 method known to those of skill in the art. Preferred methods include the spheroplast technique, described by Cregg et al. (1985) Mol. Cell. Biol. 5: 3376 and U.S. Patent No. 4,879,231, and the whole-cell lithium chloride yeast transformation system (Ito et al. (1984) Agric.
35 Biol. Chem. 48: 341), with modification necessary for

-20-

adaptation to methyl trophic yeast such as P. pastoris
(See European Patent Application No. 312,934; also
available as U.S. Patent No. 4,929,535).

If the yeast host is transformed with a linear DNA
5 fragment containing the IGF-1 gene and DNA encoding α MF
pre-pro sequences necessary for processing and secretion
under the regulation of a promoter region of a P.
pastoris gene, the expression cassette is integrated into
the host genome by any of the gene replacement techniques
10 known in the art, such as by one-step gene replacement
(see e.g., Rothstein (1983) Methods Enzymol. 101: 202;
Cregg et al. (1987) Bio/Technology 5: 479; and U.S.
Patent No. 4,882,279) or by two-step gene replacement
methods (see e.g., Scherer and Davis (1979) Proc. Natl.
15 Acad. Sci. USA, 76: 4951). The linear DNA fragment is
directed to the target gene by flanking DNA sequences
having sufficient homology with the target gene to effect
integration of the DNA fragment therein. One-step gene
disruptions are usually successful if the DNA to be
20 introduced has as little as 0.2 kb homology with the
fragment locus of the target gene; it is preferable
however to maximize the degree of homology for
efficiency.

In preferred embodiments, multiple copies of these
25 expression cassettes are included on one DNA fragment,
preferably in a head-to-tail orientation.

If the DNA fragment is included in a circular
plasmid, the plasmid may be integrated by addition rather
than gene disruption into the genome. One or more copies
30 of the plasmid can be integrated at the same or different
loci of the genome. Integration into the genome is
facilitated by linearization of the plasmid by means of a
suitable restriction endonuclease.

The DNA fragments of the expression cassette(s) are
35 said to be "operably associated" with one another. The

-21-

DNA sequence encoding IGF-1 peptides is positioned and oriented functionally with respect to the promoter, the DNA sequence encoding the S. cerevisiae α MF pre-pro sequence and the transcription terminator. Thus, the

5 polypeptide-encoding segment is transcribed under regulation of the promoter region, into a transcript capable of providing, upon translation, the desired polypeptide. Because of the presence of the α MF pre-pro sequence, the expressed IGF-1 product is secreted into

10 the culture medium. Appropriate reading frame positioning and orientation of the various segments of the expression cassette are within the knowledge of persons of ordinary skill in the art; further details are given in the Examples.

15 Positive transformants may be isolated, identified and characterized by any method known to those of skill in the art, including Southern blot analysis (Maniatis et al. (1982) Molecular Cloning: A Laboratory Manual, Cold Spring Harbor Laboratory Press, Cold Spring Harbor, New

20 York, USA) to determine, for example, the site of DNA integration; Northern blots (Maniatis et al. (1982) Molecular Cloning: A Laboratory Manual, Cold Spring Harbor Laboratory Press, Cold Spring Harbor, New York, USA ; R.S. Zitomer and B.D. Hall (1976) J. Biol. Chem.

25 251: 6320), for example, to confirm methanol-responsive IGF-1 gene expression; and product analysis to detect the presence of secreted IGF-1 peptides in the growth media.

The presently preferred host cells to be transformed with multiple expression cassettes are P. pastoris cells

30 having at least one mutation that can be complemented with a marker gene present on a transforming DNA fragment. Preferably His⁴ (GS115) or Arg⁴ (GS190) auxotrophic mutant P. pastoris strains are employed. The most preferred strains are additionally deficient in

35 expression of one or more proteases that are not required

-22-

for proper processing of the selected leader sequence. The deficiency may be manifested as an absence of or a decrease in the activity of one or more proteases by virtue of point mutations, insertions, or deletions in
5 genes that encode proteases or genes that directly or indirectly modulate expression of genes that encode proteases.

In preferred embodiments, DNA fragments containing one or more expression cassette(s) are inserted into a
10 vector containing a marker gene complementing the host's defect, and optionally containing additional sequences such as bacterial marker genes, yeast sequences which direct vector integration, and the like. Plasmids based on pBR322, such as pA0815, are preferred as vectors.
15 Insertion of one or more copies of the IGF-1 expression/secretion cassette into parent plasmid pA0815 produces plasmids such as pIGF201, pIGF202, pIGF204, pIGF206, and pIGF816.

Protease-deficient strains of P. pastoris, known as
20 pep4⁻ or pep4⁻ prb-1⁻ strains, described below and in U.S. Patent Application Serial No. 07/678,916, are among the preferred host cells. Protease-deficient P. pastoris strains are generated by disruption of P. pastoris genes, such as the PEP4 gene or PRB-1 gene, that encodes a
25 protein that directly or indirectly affects the protease activity of the cell. This disruption is preferably accomplished by the insertion of an additional plasmid, unrelated to the constructs for expression of IGF-1, into the PEP4 gene or PRB-1 gene. This disruption results in
30 a reduction of some of the protease activities in the cells, such as, for example, proteinase A, proteinase B and carboxypeptidase Y activities. This host cell strain preferably also contains a mutation which can be complemented by a marker gene carried on the expression
35 cassette, as discussed below in the Examples.

-23-

The preferred host cells may be transformed with the expression vectors that are introduced into targeted specific sites in the host cell genome in order to generate Mut⁻ expression strains of *P. pastoris*. "Mut"

5 refers to the methanol-utilization phenotype. In certain embodiments, Mut⁻ strains are prepared by first digesting the selected expression vector with an appropriate enzyme to yield a linear DNA fragment with ends homologous to the 5' and 3' ends of the AOX1 gene. The linearized DNA

10 construct expression cassette(s) is then integrated into the host genome at the AOX1 site by a one-step gene replacement technique. As a result of gene replacement of the AOX1, Mut⁻ strains are obtained. In Mut⁻ strains, strains' ability to utilize methanol is decreased. A

15 slow growth rate of the strain on methanol is maintained by expression of the AOX2 gene product. The transformants in which the expression cassette has integrated into the AOX1 locus by site-directed recombination can be identified by first screening for

20 the presence of a complementing marker gene present in the expression cassette. This is preferably accomplished by growing the cells in medium lacking the complementing gene product and identifying those cells which are able to grow by virtue of the expression of the complementing

25 gene. Next, the selected cells are screened for their "Mut" phenotype by growing them in the presence of methanol and monitoring their growth rate. Mut⁻ phenotypes have much slower growth on methanol than the parent strain.

30 To develop Mut⁺ IGF-1-expressing strains, the fragment that contains one or more expression cassette(s) preferably is integrated into the host genome by transformation of the host with a circular plasmid or a linearized plasmid containing the DNA construct. The

35 integration is by addition at a locus or loci having

-24-

homology with one or more sequences present in the fragment.

Positive transformants may be characterized by Southern analysis to identify, for example, the site of DNA integration; by Northern analysis to detect, for example, for methanol-responsive IGF-1 gene expression; and by product analysis to detect the presence of secreted IGF-1 peptides in the growth medium. Culturing transformed yeast host cells that harbor the DNA constructs.

The transformed host cells are cultured under conditions in which the DNA encoding IGF-1, signal and processing signals, is expressed, the pre-pro-peptide is processed and secreted. Transformed strains, of the desired phenotype and genotype, may be grown in large quantities by any means known to those of skill in the art. In preferred embodiments, the strains are cultured in fermentors. For the large-scale production of recombinant DNA-based products in methylotrophic yeast, a three-stage, high cell-density, fed batch fermentation system is normally the preferred fermentation protocol employed.

In the first, or growth stage, expression hosts are cultured in defined minimal medium with an excess of a non-inducing carbon source, such as but not limited to, glycerol. When grown on such carbon sources, heterologous gene expression is completely repressed, which allows the generation of cell mass in the absence of heterologous protein expression. It is presently preferred, during this growth stage, that the pH of the medium be maintained at about 5. The second stage, referred to as a period of growth under limiting conditions, refers to a short period of non-inducing carbon source limitation growth. In this stage, cell mass continues to increase and the methanol-responsive

-25-

promoter is derepressed. Although a pH of about 5 is preferred for optimal growth of P. pastoris, undetectably or low levels of IGF-1 are secreted by proteolytically intact IGF-1-expressing strains that are cultured

5 entirely at pH 5. High concentrations of IGF-1 are produced, however, if the pH of the medium during this limitation growth period is adjusted to about 4 or less, preferably in the range of about 2 - 3.5. This pH is maintained during the production phase.

10 Expression of IGF-1 from protease deficient strains is less sensitive to pH than expression from proteolytically intact strains. Protease deficient strains may be cultured entirely at pH 5. Alternatively, and preferably, protease deficient strains
15 are cultured at pH 5 during the first two stages, after which the pH is lowered to about 2.5 to about 3.0 during the third stage.

In the third stage, the production stage, either methanol alone, referred to herein as "methanol excess
20 fed-batch mode", or a limiting amount of a non-inducing carbon source plus methanol, referred to herein as "mixed-feed fed-batch mode"; are added in the fermentor. Addition of methanol induces expression of genes, including IGF-1, that are in operative linkage with
25 methanol-responsive promoters.

According to a preferred embodiment, the heterologous protein expression system used for IGF-1 production utilizes the promoter derived from the methanol-regulated AOX1 gene of P. pastoris, which is
30 tightly regulated and provides for efficient gene expression. This gene can be the source of the transcription terminator as well. The presently preferred expression cassette comprises, in operational association with one another, the P. pastoris AOX1
35 promoter, DNA encoding the S. cerevisiae α MF pre-pro

-26-

sequence including the DNA sequence encoding the processing sequence lys-arg-(glu-ala)_x, wherein x may vary from 0 to 3, a DNA sequence encoding IGF-1 polypeptides, and a transcription terminator derived from the P.

5 pastoris AOX1 gene. Preferably, two or more of such expression cassettes are contained on one DNA fragment, in head-to-tail orientation, to yield multiple expression cassettes on a single contiguous DNA fragment.

Selected methylotrophic yeast transformants that
10 have the desired genotype and phenotype are cultured in fermentors under conditions in which IGF-1 is expressed and secreted into the culture medium. It is presently preferred to use the three-step production process described above. The level of IGF-1 secreted into the
15 media can be determined by Western blot analysis of the media in parallel with an IGF-1 standard, using anti-IGF-1 antisera; by radioimmunoassay (RIA); by radio receptor assay; or by HPLC after suitable pretreatment of the medium.

20 As noted above, IGF-1 as used herein is intended to embrace all the allelic variations of IGF-1. Moreover, as noted above, derivatives obtained by simple modification of the amino acid sequence of the naturally occurring product, e.g., by way of site-directed
25 mutagenesis or other standard procedures, are included within the scope of the present invention. Forms of IGF-1 produced by proteolysis of host cells that exhibit similar biological activities to naturally occurring IGF-1 are also encompassed by the present invention.

30 The following examples are included for illustrative purposes only and are not intended to limit the scope of the invention.

EXAMPLES

P. pastoris is described herein as a model system
35 for the use of methylotrophic yeast hosts. Methylotrophic

-27-

yeast host cells from four genera: Candida, Hansenula, Pichia and Torulopsis may also be used. Host cells from any species that demonstrably grows on methanol as the sole carbon nutrient may be used (see, e.g., Gleeson et al. (1988) Yeast 4: 1). Such species may be used as described herein for P. pastoris.

EXAMPLE 1

CONSTRUCTION OF THE PICHIA PASTORIS EXPRESSION VECTORS USED IN THE PREPARATION OF THE IGF-1 EXPRESSION VECTORS.

10 A. Construction of plasmid pAO203.

Plasmid pAO203 contains a 5' EcoRI-3' HindIII DNA fragment encoding the α MF pre-pro region, the amino acids of protease processing sites, lys-arg and (glu-ala)₂ and the AOX1 transcription terminator.

15 The AOX1 transcription terminator was isolated from pPG2.0. Plasmid pPG2.0 had been prepared by inserting the BamHI-HindIII fragment of pG4.0 (NRRL 15868), which contains the AOX1 terminator, into pBR322. 20 μ g of pPG2.0 was digested with StuI, followed by the addition of 0.2 μ g SalI linkers (GGTCGACC). The plasmid was subsequently digested with HindIII and the 350 bp HindIII-SalI fragment was isolated from a 10% acrylamide gel and subcloned into pUC18 (Boehringer Mannheim) that had been digested with HindIII and SalI. The ligation mix was transformed into JM103 cells and Amp^r colonies were selected. The correct construction was verified by HindIII and SalI digestion, which yielded a 350 bp fragment, and was called pAO201.

25 5 μ g of pAO201 was digested with HindIII, filled in using E. coli DNA Polymerase I Klenow fragment, and 0.1 μ g of BglII linkers (GAGATCTC) were added. After digestion of the excess BglII linkers, the plasmid was reclosed and transformed into MC1061 cells. Amp^r cells were selected, DNA was prepared, and the correct plasmid was verified by BglII, SalI double digests, which yielded

35

-28-

the expected 350 bp fragment, and by a HindIII digest, which showed loss of a HindIII site. This plasmid was designated pA0202.

An alpha factor-GRF fusion was isolated as a 360 bp
5 BamHI-PstI partial digest from pYSV201. Plasmid pYSV201 had been prepared by inserting the EcoRI-BamHI fragment of GRF-E-3, which is described in European Patent Application No. 206,783, into M13mp18 (New England Biolabs). 20 µg of pYSV201 plasmid was digested with
10 BamHI and partially digested with PstI. The following oligonucleotides were added to this partial digest:
5' AATTCGATGAGATTTTCCTTCAATTTTACTGCA 3' (Seq. ID No. 8)
3' GCTACTCTAAAGGAAGTTAAAAATG 5' (Seq. ID No. 9).

Only the antisense strand of the oligonucleotide was
15 kinase labelled so that the oligonucleotides did not polymerize at the 5'- end. A 350 bp fragment was isolated by electroelution following acrylamide gel electrophoresis (10%). This EcoRI- BamHI fragment of 385 bp was cloned into pA0202 which had been cut with EcoRI
20 and BamHI. MC1061 cells were transformed and Amp^r cells were selected. The resulting plasmid, pA0203, was identified by cutting with EcoRI and BglII to yield a fragment of greater than 700 bp.

B. Construction of plasmid pA0807.

25 1. Preparation of fl-ori DNA.

Bacteriophage fl DNA (50 µg) was digested with 50 units of RsaI and DraI to release the ≈458 bp DNA fragment containing the fl origin of replication (ori). The digestion mixture was extracted with an equal volume
30 of phenol:chloroform (V/V) followed by extracting the aqueous layer with an equal volume of chloroform and finally the DNA in the aqueous phase was precipitated by adjusting the NaCl concentration to 0.2M and adding 2.5 volumes of absolute ethanol. The mixture was allowed to
35 stand on ice (4°C) for 10 minutes and the DNA precipitate

-29-

was collected by centrifugation for 30 minutes at 10,000 x g in a microfuge at 4°C.

The DNA pellet was washed 2 times with 70% aqueous ethanol. The washed pellet was vacuum dried and dissolved in 25 µl of TE buffer (1.0 mM EDTA in 0.01 M (pH 7.4) Tris buffer). This DNA was electrophoresed on 1.5% agarose gel and the gel portion containing the ≈458 bp fl-ori fragment was excised out and the DNA in the gel was electroeluted onto DE81 (Whatman) paper and eluted from the paper in 1M NaCl. The DNA solution was precipitated as detailed above and the DNA precipitate was dissolved in 25 µl of TE buffer (fl-ori fragment).

2. Cloning of fl-ori into DraI sites of pBR322.

Plasmid pBR322 (2 µg) was partially digested with 2 units of DraI . The reaction was terminated by phenol:chloroform extraction followed by precipitation of DNA as detailed in step 1 above. The DNA pellet was dissolved in 20 µl of TE buffer. About 100 ng of this DNA was ligated with 100 ng of fl-ori fragment (step 1) in 20 µl of ligation buffer by incubating at 14°C for overnight with 1 unit of T4 DNA ligase. The ligation was terminated by heating to 70°C for 10 minutes and then used to transform E. coli strain JM103 (Janisch-Perron et al. (1983) Gene 22: 103). Amp^R transformants were pooled and superinfected with helper phage R408. Single stranded phage were isolated from the media and used to reinfect JM103. Amp^R transformants contained pBRfl-ori which contains fl-ori cloned into the Dra I sites (nucleotide positions 3232 and 3251) of pBR322.

3. Construction of the plasmid pA0807.

Plasmid pBRfl-ori (10 µg) was digested for 4 hours at 37°C with 10 units each of Pst I and Nde I. The digested DNA was phenol:chloroform extracted, precipitated and dissolved in 25 µl of TE buffer, as

-30-

detailed in step 1 above. This material was electrophoresed on a 1.2% agarose gel and the Nde I - Pst I fragment (approximately 0.8 kb) containing the fl-ori was isolated and dissolved in 20 μ l of TE buffer as detailed in step 1 above. About 100 ng of this DNA was mixed with 100 ng of pA0804, which had been prepared as described in published International Patent Application No. WO 89/04320, May 18, 1989 and below and which had been digested with PstI and NdeI and phosphatase-treated. This mixture was ligated in 20 μ l of ligation buffer by incubating overnight at 14°C with 1 unit of T4 DNA ligase. The ligation reaction was terminated by heating at 70°C for 10 minutes. This DNA was used to transform E. coli strain JM103 to obtain pA0807.

15 C. Construction of plasmid pA0804:

Plasmid pA0804 has been described in published International Patent Application No. WO 89/04320, May 18, 1989. Construction of this plasmid involved the following steps:

20 Plasmid pBR322 was modified as follows to eliminate the EcoRI site and insert a BglII site into the PvuII site. Plasmid pBR322 was digested with EcoRI, the protruding ends were filled in with Klenow Fragment of E. coli DNA polymerase I, and the resulting DNA was recircularized using T4 ligase. The recircularized DNA was used to transform E. coli MC1061 to ampicillin-resistance and transformants were screened for having a plasmid of about 4.37 kbp in size without an EcoRI site. One such transformant was selected and cultured to yield a plasmid, designated pBR322 Δ RI, which is pBR322 with the EcoRI site replaced with the sequence:

5'-GAATTAATTC-3'

3'-CTTAATTAAG-5'.

Plasmid pBR322 Δ RI was digested with PvuII, and the linker having the sequence:

-31-

5'-CAGATCTG-3'

3'-GTCTAGAC-5'

was ligated to the resulting blunt ends employing T4 ligase. The resulting DNAs were recircularized, also with T4 ligase, and then digested with BglII and again recircularized using T4 ligase to eliminate multiple BglII sites due to ligation of more than one linker to the PvuII-cleaved pBR322 Δ RI. The DNAs, treated to eliminate multiple BglII sites, were used to transform E. coli MC1061 to ampicillin-resistance. Transformants were screened for a plasmid of about 4.38 kbp with a BglII site. One such transformant was selected and cultured to yield a plasmid, designated pBR322 Δ RIBGL, for further work. Plasmid pBR322 Δ RIBGL is the same as pBR322 Δ RI except that pBR322 Δ RIBGL has the sequence

5'-CAGCAGATCTGCTG-3' (Sequence ID No. 11)

3'-GTCGTCTAGACGAC-5' (Sequence ID No. 12)

in place of the PvuII site in pBR322 Δ RI.

Plasmid pBR322 Δ RIBGL was digested with a SalI and BglII and the large fragment (approximately 2.97 kbp) was isolated. Plasmid pBSAGI5I, which is described, for example, in European Patent Application Publication No. 0 226 752, was digested completely with BglII and XhoI and an approximately 850 bp fragment from a region of the P. pastoris AOX1 locus downstream from the AOX1 gene transcription terminator (relative to the direction of transcription from the AOX1 promoter) was isolated. The BglII-XhoI fragment from pBSAGI5I and the approximately 2.97 kbp, SalI-BglII fragment from pBR322 Δ RIBGL were combined and subjected to ligation with T4 ligase. The ligation mixture was used to transform E. coli MC1061 to ampicillin-resistance and transformants were screened for a plasmid of the expected size (approximately 3.8 kbp) with a BglII site. This plasmid was designated pA0801. The overhanging end of the SalI site from the

-32-

pBR322 Δ RIBGL fragment was ligated to the overhanging end of the XhoI site on the 850 bp pBSAGI5I fragment and, in the process, both the SalI site and the XhoI site in pA0801 were eliminated.

5 Plasmid pBSAGI5I was then digested with ClaI and the approximately 2.0 kbp fragment was isolated. The 2.0 kbp fragment has an approximately 1.0-kbp segment which comprises the P. pastoris AOX1 promoter and transcription initiation site, an approximately 700 bp segment encoding
10 the hepatitis B virus surface antigen (HBsAg) and an approximately 300 bp segment which comprises the P. pastoris AOX1 gene polyadenylation signal and site-encoding segments and transcription terminator. The HBsAg coding segment of the 2.0 kbp fragment is
15 terminated, at the end adjacent the 1.0 kbp segment with the AOX1 promoter, with an EcoRI site and, at the end adjacent the 300 bp segment with the AOX1 transcription terminator, with a StuI site, and has its subsegment which codes for HBsAg oriented and positioned, with
20 respect to the 1.0 kbp promoter-containing and 300 bp transcription terminator-containing segments, operatively for expression of the HBsAg upon transcription from the AOX1 promoter. The EcoRI site joining the promoter segment to the HBsAg coding segment occurs just upstream
25 (with respect to the direction of transcription from the AOX1 promoter) from the translation initiation signal-encoding triplet of the AOX1 promoter.

Plasmid pA0801 was cut with ClaI and mixed with T4 ligase and the approximately 2.0 kbp ClaI-site-terminated
30 fragment from pBSAGI5I. The ligation mixture was used to transform E. coli MC1061 to ampicillin resistance, and transformants were screened for a plasmid of the expected size (approximately 5.8 kbp) which, upon digestion with ClaI and BglII, yielded fragments of about 2.32 kbp (with
35 the origin of replication and ampicillin-resistance gene

-33-

from pBR322) and about 1.9 kbp, 1.48 kbp, and 100 bp. On digestion with BglII and EcoRI, the plasmid yielded an approximately 2.48 kbp fragment with the 300 bp terminator segment from the AOX1 gene and the HBsAg coding segment, a fragment of about 900 bp containing the segment from upstream of the AOX1 protein encoding segment of the AOX1 gene in the AOX1 locus, and a fragment of about 2.42 kbp containing the origin of replication and ampicillin resistance gene from pBR322 and an approximately 100 bp ClaI-BglII segment of the AOX1 locus (further upstream from the AOX1-encoding segment than the first mentioned 900 bp EcoRI-BglII segment). Such a plasmid had the ClaI fragment from pBSAGI5I inserted in the desired orientation. Had it been inserted in the opposite undesired orientation, there would have been EcoRI-BglII fragments of about 3.3 kbp, 2.38 kbp and 900 bp. One of the transformants harboring the desired plasmid, designated pA0802, was selected for further work and was cultured to yield that plasmid.

Plasmid pA0802 was then treated to remove the HBsAg coding segment terminated with an EcoRI site and a StuI site. The plasmid was digested with StuI and a linker of sequence:

5'-GGAATTCC-3'
3'-CCTTAAGG-5'

was ligated to the blunt ends using T4 ligase. The mixture was then treated with EcoRI and again subjected to ligating using T4 ligase. The ligation mixture was used to transform E. coli MC1061 to ampicillin resistance and transformants were screened for a plasmid of the expected size (5.1 kbp) with EcoRI-BglII fragments of about 1.78 kbp, 900 bp, and 2.42 kbp and BglII-ClaI fragment of about 100 bp, 2.32 kbp, 1.48 kbp, and 1.2 kbp. A transformant with the desired plasmid was

-34-

selected for further work and was cultured to yield pA0803.

Plasmid pA0804 was prepared from pA0803 by inserting, into the BamHI site from pBR322 in pA0803, an approximately 2.75 kbp BglII fragment from the P. pastoris HIS4 gene. See, e.g., Cregg et al. (1985) Mol. Cell. Biol. 5, 3376 and European Patent Application Publication Nos. 180,899 and 188,677. Plasmid pA0803 was digested with BamHI and combined with the HIS4 gene-
10 containing BglII site-terminated fragment and the mixture subjected to ligation using T4 ligase. The ligation mixture was used to transform E. coli MC1061 to ampicillin-resistance and transformants were screened for a plasmid of the expected size (7.85 kbp), which is cut
15 by SalI. One such transformant was selected for further work, and the plasmid it harbors was designated pA0804.

Plasmid pA0804 has one SalI-ClaI fragment of about 1.5 kbp and another of about 5.0 kbp and a ClaI-ClaI fragment of 1.3 kbp, indicating that the direction of
20 transcription of the HIS4 gene in the plasmid is the same as the direction of transcription of the ampicillin resistance gene and opposite to the direction of transcription from the AOX1 promoter.

The orientation of the HIS4 gene in pA0804 is not
25 critical to the function of the plasmid or any derivatives that include heterologous DNA fragments inserted at the EcoRI site between the AOX1 promoter and terminator fragments. Thus, a plasmid with the HIS4 gene in the orientation opposite to that of the HIS4 gene in
30 pA0804 could be used in place of pA0804.

D. Construction of plasmid pA0815

Plasmid pA0815 was constructed by mutagenizing plasmid pA0807 to change the ClaI site downstream from the AOX1 transcription terminator in pA0807 into a BamHI
35 site. The oligonucleotide used for mutagenizing pA0807

-35-

had the following sequence:

5'-GAC GTT CGT TTG TGC GGA TCC AAT GCG GTA GTT TAT-3'
(Sequence ID No. 10).

The mutagenized plasmid was designated pA0807-Bam.

- 5 Plasmid pA0804 (described above and in International Patent Application WO 89/04320) was digested with BglII and 25 ng of the 2400 bp fragment were ligated to 250 ng of the 5400 bp BglII fragment from BglII-digested pA0807-Bam. The ligation mix was transformed into MC1061 cells
10 and the correct construct was verified by digestion with PstI/BamHI to identify 6100 and 2100 bp sized bands. The correct construct was called pA0815. The restriction map of the expression vector pA0815 is shown in Figure 7.

EXAMPLE 2

15 CONSTRUCTION OF VECTORS FOR EXPRESSION OF IGF-1 IN P. PASTORIS.

- The expression vector constructions were carried out using standard procedures, as described, for example by Maniatis et al. ((1982) Molecular Cloning: A Laboratory
20 Manual, Cold Spring Harbor Laboratory Press, Cold Spring Harbor, New York, USA) and Davis et al. ((1986) Basic Methods in Molecular Biology, Elsevier Science Publishing, Inc., New York).

25 A. Construction of expression vectors that contain DNA encoding α MF prepro-lys-arg-IGF-1.

- Expression vectors were prepared that contain one or multiple copies of the IGF-1 gene expression cassette, 5' AOX1- α MF prepro-lys-arg-IGF-1 - 3' AOX1, in which the α MF prepro-encoding element contains the α MF prepro-lys-arg
30 but lacks glu-ala spacer-encoding nucleotides.

1. Construction of pIGF201 which contains a single copy of the expression cassette.

- The synthetic gene encoding human IGF-1 shown in Figure 1 as a HindIII-BamHI fragment, was incorporated
35 into vect r pUC18 and was used to transform E. coli strain MC1061. Ampicillin-resistant transformants were

-36-

selected and screened by examination of restriction enzyme-digested DNA for the presence of a HindIII-BamHI insert of approximately 240 bp, the size expected for the IGF-1 gene. One transformant with an insert of this size
5 was used to prepare plasmid DNA designated pIGF101.

The 240 bp HindIII-BamHI fragment (250 ng) isolated from pIGF101, containing the IGF-1 gene, was inserted into the HindIII-BamHI site of plasmid pAO203 (10 ng), which contains DNA encoding an EcoRI site at the 5' end,
10 the α MF pre-pro region, followed by nucleotides which encode the amino acids for three processing sites, lys-arg and (glu-ala)₂, and including a HindIII site at the 3' end. The resulting plasmid was used to transform E. coli MC1061 cells. Ampicillin-resistant colonies were
15 selected and screened with an oligonucleotide complementary to sequence 162 to 132 of the IGF-1 gene, Sequence ID No. 1. One colony which was positive in this screen was selected and its plasmid designated pIGF102.

The EcoRI-BamHI fragment from pIGF102 (250 ng),
20 containing the α MF pre-pro region and proteolytic processing sites, and IGF-1 gene, was cloned into M13mp19 (10 ng) and used to transform E. coli JM103 cells. The resulting transformants were screened by analysis of restriction enzyme-digested DNA, and one clone (pIGF103)
25 with an insert of the correct size (480 bp EcoRI-BamHI fragment) was used to prepare single-stranded DNA for site-directed mutagenesis. Site-directed mutagenesis of the single-stranded DNA was performed to delete the (glu-ala)₂ spacer sites, the HindIII cloning site, the
30 polylinker attached to the synthetic gene, and the codon for the initial methionine of IGF-1. Mutagenesis was accomplished using standard procedures and oligonucleotides having the following sequences:

mutagenizing oligonucleotide (Sequence ID No.

35 2):

-37-

5'-GTATCTTTGGATAAAAAGAGGACCGGAGACGCTCTGC-3'

screening oligonucleotide (Sequence ID No. 3):

5'-ATAAAAGAGGACCGGA-3'.

Removal of the above noted sequences yielded a fusion
5 gene containing DNA encoding the α MF pre-pro region and
lys-arg processing site fused directly to the coding
region of the IGF-1 gene.

The selected clone, designated pIGF104, was
sequenced to verify the changes and then subjected to a
10 second site-directed mutagenesis to insert an EcoRI site
immediately following the translation termination codon
of the IGF-1 gene. Oligonucleotides having sequences as
follows were used in this mutagenesis:

mutagenizing oligonucleotide (Sequence ID No.
15 4):

5'-AGTCAGCTTGATAAGAATTCAAATGAGTCGACCTGCAGGC-3'

screening oligonucleotide (Sequence ID No. 5):

5'-TAAGAATTCAAATGAGT-3'.

The mutagenized clone was designated pIGF105.

20 After the second mutagenesis was confirmed by DNA
sequencing, the α MF-IGF-1 gene fusion was isolated on a
450 bp EcoRI fragment, then 250 ng of this EcoRI fragment
was inserted into 10 ng of the P. pastoris expression
vector pA0815, which had been previously digested with
25 EcoRI and treated with calf alkaline phosphatase. The
resulting single-copy expression vector, pIGF201,
contains one copy of the α MF-IGF-1 fusion gene under the
transcriptional control of the Pichia pastoris AOX1
promoter and regulatory regions, as well as the AOX1
30 transcription termination and polyadenylation signals.
In addition, the vector includes the Pichia pastoris HIS4
gene used for selection in His⁻ hosts and additional 3'
AOX1 sequences which can be used to direct integration of
the vector into the host genome. Plasmid pIGF201 is
35 sh wn in Figure 2.

-38-

The entire α MF-IGF-1 fusion gene and approximately 50 nucleotides each of the promoter and termination regions of pIGF201 were sequenced to verify that the nucleotide sequences were not altered during the cloning process.

2. Construction of expression vectors pIGF202, pIGF204, and pIGF206, which contain a multiple copies of the expression cassette.

The expression cassette containing the AOX1 promoter and regulatory region, the α MF-IGF-1 fusion gene, and the AOX1 transcription termination and polyadenylation signals was isolated from pIGF201 as a 1700 bp BglIII-BamHI fragment. The BglIII-BamHI expression cassette (250 ng) was inserted back into the unique BamHI site of pIGF201 (10 ng of BamHI digested, calf alkaline phosphatase-treated pIGF201). MC1061 cells were transformed with the ligation. Amp^R colonies were selected and plasmid was characterized by restriction digest. Analysis of restriction enzyme digests of the resulting plasmid, pIGF202 shown in Figure 3, verified that the two expression cassettes were joined as tandem-repeat units rather than inverted-repeat units: SalI digest yielded ~2100, 1750, and 6100 bp bands; ClaI/BamHI digest yielded ~3800 and 6450 bp bands.

The BglIII-BamHI fragment from plasmid pIGF202, containing two copies of the expression cassette, was isolated (250 ng) and inserted back into the unique BamHI site in calf alkaline phosphatase-treated pIGF202 (10 ng) to yield vector pIGF204 shown in Figure 4, containing four copies of the expression cassette. MC1061 cells were transformed with the ligation. Amp^R colonies were selected and plasmid was characterized by restriction digest. Correct plasmid demonstrated ~6600 and 6900 bp bands upon digestion with ClaI and BamHI.

To construct expression vector pIGF206, which contains six copies of the expression cassette, the

-39-

BglII-BamHI fragment from pIGF202 (250 ng) was cloned into the BamHI site of pIGF204 (10 ng; pIGF204 had been previously treated with calf alkaline phosphatase). MC1061 cells were transformed with the ligation. Amp^R colonies were selected and plasmid was characterized by restriction digest. Restriction digests of the vector DNA were examined to verify the number of expression cassettes and that the expression cassettes were joined as tandem-repeat units. Correct plasmid yielded bands of 10 ~6600 and 10300 bp upon digestion with ClaI and BamHI. Plasmid pIGF206 is shown in Figure 5.

B. Construction of expression vectors containing α MF prepro-lys-arg-glu-ala-IGF-1.

IGF-1 expression vectors containing DNA encoding the 15 α MF prepro sequence, including the lys-arg and one glu-ala processing sequence, fused to the IGF-1 coding sequence were prepared from pIGF105, which contains the α MF prepro-lys-arg-IGF-1 fusion gene in M13mp19 (see Example 2.A.1). Site-directed mutagenesis of single- 20 stranded DNA from pIGF105 was performed to insert codons for a glu-ala spacer site between the α MF prepro-lys-arg and IGF-1 DNA sequences. Mutagenesis was accomplished using standard procedures and oligonucleotides having the following sequences:

25 **Mutagenizing oligonucleotide (Sequence ID No. 6)**

5'-TCTTTGGATAAAGAGAGGCTGGACCGCAGACGCTC-3'

Screening oligonucleotide (Sequence ID No. 7)

5'-AAAAGAGAGGCTGGACCGC-3'.

The selected clone was sequenced to verify that the DNA 30 encoding the glu-ala residues was added correctly. The α MF prepro-lys-arg-glu-ala-IGF-1 gene fusion was isolated from the selected clone on a 465-bp EcoRI fragment and ligated to EcoRI-digested, alkaline phosphatase-treated vector pA0815. The resulting single copy expression 35 vector, pIGF816, contains on c py of the α MF prepro-lys-

-40-

arg-glu-ala-IGF-1 gene fusion under transcriptional control of the P. pastoris AOX1 promoter and regulatory regions, as well as the AOX1 transcription termination and polyadenylation signals. The vector also includes
5 the P. pastoris HIS4 gene for selection in His⁺ hosts and additional AOX1 sequences. The entire α MF prepro-lys-arg-glu-ala-IGF-1 gene fusion and approximately 30 nucleotides each of the promoter and termination regions of pIGF816 were sequenced to verify that the sequences
10 were not altered during the cloning process.

Expression vectors containing two or more copies of the α MF prepro-lys-arg-glu-ala-IGF-1 gene cassette can be prepared as described for construction of vectors containing multiple copies of the α MF prepro-lys-arg-IGF-
15 1 gene expression cassette (see Example 2.A.2.).

EXAMPLE 3

INTRODUCTION OF THE EXPRESSION CASSETTES FROM THE IGF-1 EXPRESSION VECTORS INTO STRAINS OF PICCHIA PASTORIS.

A. Mut⁺ strains

20 Expression vectors pIGF201, pIGF202, pIGF204, and pIGF206 and pIGF816 were used to develop IGF-1-expressing Mut⁺ strains of Pichia pastoris. The Mut phenotype refers to the methanol utilization ability of the strain. Mut⁺ strains consume methanol at a rate similar to that of
25 wild-type strains. A HIS4 mutant of Pichia pastoris, GS115 (ATCC No. 20864), was used as the host for all transformations, which were accomplished by either the spheroplast method (performed as described in U.S. Patent No. 4,879,231) or by the whole-cell lithium chloride
30 yeast transformation system (Ito, et al. (1984) Agric. Biol. Chem. 48: 341) with modification necessary for adaptation to methylotrophic yeast, such as P. pastoris (see European Patent Application No. 312,934; also available as U.S. Patent No. 4,929,535).

35 Mut⁺ strains were generated by integration of the

-41-

entire expression vector into either the AOX1 or HIS4 locus of the host genome by an additive homologous recombination event. Plasmid pIGF201 was transformed into GS115 as an undigested circular vector and allowed to integrate randomly into the AOX1 locus at either the 5' or 3' regions homologous to sequences contained in the plasmid, or into the HIS4 locus. For site-directed addition to the HIS4 locus, the multi-copy expression vectors pIGF202, pIGF204, and pIGF206 and the single copy vector pIGF816 were digested with StuI, which linearizes the plasmids by cutting the vector within the HIS4 region. Additive integration at either the AOX1 or HIS4 locus does not disturb the AOX1 gene.

The Mut⁺ transformants resulting from additive integration of the expression plasmids, either randomly (pIGF201) or by site-direction (pIGF202, pIGF204, pIGF206 and pIGF816), were initially screened for histidine prototrophy. Prototrophic strains generated by separate transformation of GS115 with each of the four plasmids were selected for further analysis.

Ten of the His⁺ transformants resulting from transformation of GS115 with pIGF201 were analyzed by Southern blot hybridization to verify the site of integration of the expression plasmid and number of copies of the plasmid integrated. Chromosomal DNA from the 10 transformants was separately digested with EcoRI and BglII, separated by agarose gel electrophoresis, and transferred to nitrocellulose. The EcoRI digests were probed with pBR322-based plasmids containing either the AOX1 5' and 3' regions or the *Pichia pastoris* HIS4 gene. The BglII digest was probed with an oligonucleotide homologous to the IGF-1 gene.

Sixteen of the His⁺ transformants generated by transformation of GS115 with pIGF202, 16 generated by transformation with pIGF204, and 26 generated by

-42-

transformation with pIGF206 were also analyzed by Southern blot hybridization to verify the site of integration and integrity of the multi-copy expression vector. Chromosomal DNA was digested with BglII and
 5 probed with plasmids containing the AOX1 5' and 3' regions or HIS4 gene, and also separately digested with StuI and probed with the oligonucleotide homologous to the IGF-1 coding sequence.

Analysis of DNA from ten pIGF201 transformants by
 10 Southern blot hybridization indicated that four transformants contained a single copy of the expression vector integrated at the AOX1 locus and two transformants contained multiple copies of the plasmid integrated at the HIS4 locus. The four other strains contained the
 15 plasmid integrated at unknown loci. It was not possible to determine the exact number of copies of the plasmid integrated at HIS4. Southern analysis of DNA revealed that 10 of the pIGF202 transformants, 9 of the pIGF204 transformants, and 13 of the 26 pIGF206 transformants
 20 contained a single copy of the respective expression vector integrated at HIS4. The other transformants contained plasmids integrated at unknown loci.

The following representative strains generated by transformation of GS115 with vectors pIGF201, pIGF202,
 25 pIGF204 or pIGF206 were selected for further analysis:

Strain Name	Plasmid Integrated	Site of Integration	Number of Plasmids Integrated	Expression Cassette Copy Number
30 G+IGF201S1	pIGF201	<u>AOX1</u>	1	1
G+IGF206S2	pIGF206	<u>HIS4</u>	1	6
G+IMB202S2	pIGF202	<u>HIS4</u>	1	2
G+IMB204S14	pIGF204	<u>HIS4</u>	1	4
G+IMB206S1	pIGF206	<u>HIS4</u>	1	6

35

In addition, four strains generated by

-43-

transformation with pIGF816, strains G+IGF816S1, G+IGF816S2, G+IGF816S9 and G+IGF816S11, were also analyzed further during growth in one-liter fermentations.

5 B. Mut⁻ strains

In Mut⁻ strains, the expression vector integrates into the AOX1 locus and disrupts it. Thus, Mut⁻ strains consume methanol at a much slower rate than Mut⁺ strains.

To generate Mut⁻ strains, plasmid pIGF206 was
10 digested with BglII. This liberates a fragment comprised of the six IGF-1 expression cassettes, the HIS4 gene for selection, and the AOX1 3' region. Both ends of this fragment contain long sequences which are homologous to the 5' and 3' ends of the AOX1 locus. Upon
15 transformation of GS115 hosts with the BglII-ended fragment, integration into the AOX1 locus by homologous recombination results in substitution of the BglII-ended fragment for the AOX1 structural gene. Positive transformants were selected by their His⁺ phenotype and
20 by their Mut⁻ phenotype, slow growth on methanol. Selection is accomplished by plating His⁺ transformants on minimal glucose (2%) master plates to obtain colonies originating from single cells. After overnight incubation at 30°C, the masters were replica-plated to
25 minimal glucose plates and plates containing no carbon source to which methanol was added in vapor phase. This is accomplished by adding approximately 200 µl of methanol to the underside of the top of a covered petri dish. The plates were incubated at 30°C for 4-6 days
30 with additional methanol added in the vapor phase every two days. Colonies showing visible growth were scored as Mut⁺ and those with no visible, or slow, growth were scored as Mut⁻. Approximately 15% were slow growers, which is indicative of disruption of the AOX1 gene.

35 Following the initial screening for methanol

-44-

utilization and histidine prototr phy, chromosomal DNA from three Mut⁻ transformants was analyzed by three different Southern blots to verify the site of plasmid integration and number of copies integrated.

- 5 Chromosomal DNA from Mut⁻ transformants was digested with EcoRI and probed with pBR322-based plasmids containing either the AOX1 5' and 3' regions or the *Pichia pastoris* HIS4 gene. An additional blot of BglII-digested DNA was probed with the plasmid containing the
- 10 IGF-1 gene. Southern analysis of the three Mut⁻ transformants generated using plasmid pIGF206 revealed that all three contained a single copy of the BglII fragment, containing six expression cassettes, integrated by replacement at the AOX1 locus.

- 15 The strains were characterized as follows:

	Strain Name	Site of Integration	Number of Plasmids Integrated	Expression cassette copy number
	G-IMB206S1	<u>AOX1</u>	1	6
20	G-IMB206S2	<u>AOX1</u>	1	6
	G-IMB206S3	<u>AOX1</u>	1	6

C. Preparation of protease-deficient strains for expression and secretion of IGF-1.

- 25 The use of protease -deficient strains of *P. pastoris* hosts for recombinant expression of heterologous proteins susceptible to degradation by *P. pastoris* proteases is described in U.S. Patent Application No. 07/678,916. Protease-deficient *P. pastoris* strains have
- 30 been generated by disrupting *P. pastoris* genes, such as PEP4 and PRB-1, that encode proteins that directly or indirectly affect protease activity of the cell. Disruption of these genes results in a reduction of at least a portion of the protease activities in the cell,
- 35 including proteinase A, carboxypeptidase Y and proteinase B activities. Recombinant Pep4⁻ (also called pep4) and Pep4⁻Prb-1⁻ (also called pep4 prb-1 IGF-1-secreting

-45-

strains of P. pastoris have been prepared.

Four protease-deficient IGF-1 expressing strains of P. pastoris, strains M+IMB206S1, M+IGF816S1, M+IGF816S4 and C+IGF816S1 were generated using two different approaches. Strain M+IMB206S1 was developed by transformation of a P. pastoris strain containing six copies of an α MF prepro-lys-arg-IGF-1 gene expression cassette (strain G+IMB206S1, see Example 3.A.) with a PEP4 gene disruption vector, pDR421. Vector pDR421 (described below and in detail in U.S. Patent Application Serial No. 07/678,916) contains an internal portion of the P. pastoris PEP4 gene which integrates into the host genome at the PEP4 locus to generate two incomplete and nonfunctional copies of the PEP4 gene.

Strains M+IGF816 S1, M+IGF816S4 and C+IGF816S1 were generated by transforming protease deficient P. pastoris host strains with the α MF prepro-lys-arg-glu-ala-IGF-1 gene construct. Strains M+IGF816S1 and M+IGF816S4 were generated by transformation of a pep4 host and C+IGF816S1 by transformation of a pep4, prb-1 host.

1. Construction of the P. pastoris PEP4 gene disruption vector pDR421.

Plasmid pDR421 was constructed for use in the preparation of PEP4-deficient (Pep4⁻) strains of P. pastoris in which the host PEP4 gene is disrupted by addition of an incomplete PEP4 gene to the endogenous PEP4 locus. Plasmid pDR421 contains an internal portion of the PEP4 gene, which, when introduced into the host genome at the PEP4 locus, results in two incomplete and nonfunctional copies of the PEP4 gene.

To construct pDR421, the URA3 gene of P. pastoris was cloned into vector pEP205. Plasmid pEP205 contains pUC19 sequences and the portion of the PEP4 gene encoded by the approximately 450 bp BamHI fragment derived fr m

-46-

pep202. Plasmid pep202 was prepared by inserting a 10.6 kb EcoRI fragment of the P. pastoris genome, that had been identified as containing the PEP4 gene by Southern blot hybridization of EcoRI-digested P. pastoris genomic DNA with the homologous S. cerevisiae PEP4 gene as a probe, into pUC19. The 10.6 kb fragment was isolated and approximately 200 ng of it was ligated with an equal amount of pUC19 which had been cut with EcoRI and dephosphorylated. The ligation mixture was used to transform E. coli strain MC1061. Ampicillin-resistant colonies were selected and screened by analysis of restriction enzyme digests of colony DNA for the presence of the diagnostic 10.6 kb EcoRI fragment. A large-scale plasmid preparation was made from a colony containing the correct plasmid, which was named pep202. Plasmid pep202 contains the complete P. pastoris PEP4.

The URA3 gene was isolated from SpeI/SphI digested pPU205 as a 2 kb fragment and ligated to XbaI/SphI-digested pep205 and used to transform E. coli strain MC1061 to ampicillin resistance. Amp^r colonies were screened by analysis of BamHI/SphI digested colony DNA for the presence of 2.7kb, 0.4 kb and 1.9 kb fragments. A selected transformant that contained the correct plasmid construct was identified and the plasmid was designated pDR421.

2. Preparation of M+IMB206S1

M+IMB206S1, a pep4 IGF-1 expressing strain, was generated by transforming a pep4 P. Pastoris strain that contained six copies of an α MF prepro-lys-arg-IGF-1 construct with the PEP4 disruption vector pDR421, which contains an internal portion of the P. pastoris PEP4 gene and which integrates into the host genome at the PEP4 locus, thereby disrupting expression of the gene by generating two incomplete and nonfunctional copies of the gene.

-47-

In order to facilitate identification of transformants that incorporated pDR421, an auxotrophic marker selection system was established in strain G+IMB206S1 prior to transformation. This was accomplished by isolation of a colony of G+IMB206S1 that, through spontaneous mutation, became auxotrophic for uracil (Ura⁻). Because pDR421 contains a P. pastoris URA3 marker gene, in addition to the PEP4 fragment, it was possible to initially select those cells of the Ura⁻ derivative of G+IMB206S1 that had incorporated pDR421 on the basis of uracil prototrophy. The isolation of a Ura⁻ IGF-1-expressing P. pastoris strain and its use in generating a PEP4 IGF-1-expressing P. pastoris strain are described in this section.

a. Isolation of the Ura⁻ IGF-1 expressing strain IGF-U.

Resistance to a 5-fluoro-orotic acid (5-FOA) was used as a means of identifying Ura⁻ derivatives of strain G+IMB206S1. 5-FOA is an analog of a uracil biosynthetic pathway intermediate that, when metabolized by Ura⁺ strains, yields a toxic compound. Therefore, Ura⁺ strains cannot survive on 5-FOA-containing medium. In contrast, the uracil biosynthetic pathway of Ura⁻ strains is blocked at certain steps, and such strains do not metabolize 5-FOA and are unaffected by its toxic effects. Consequently, plating cells on 5-FOA-containing medium can be used as a method to detect Ura⁻ strains generated by spontaneous mutation.

A Ura⁻ derivative of the IGF-1-producing strain G+IMB206S1 is isolated by direct plating of approximately 5×10^7 cells into a 5-FOA-containing medium supplemented with uracil (0.67% yeast nitrogen base, 2% agarose, 2% glucose, 750 mg/L of 5-FOA and 45 mg/L of uracil). After one week of incubation at 30°C, a colony growing on the plate was isolated. This colony, which

-48-

required uracil to grow, was unable to complement a ura3 strain of Pichia pastoris and was designated IGF-U.

b. Transformation of IGF-U with pDR421

Plasmid pDR421 contains the Pichia URA3 gene and a
5 small portion of the Pichia PEP4 gene. BglII-digested
plasmid pDR421 was used to transform IGF-U using standard
spheroplast transformation procedures. Digestion of
pDR421 with BglII linearized the vector by cleaving it
within the PEP4 gene fragment. Thus, the resulting
10 linear DNA had 5' and 3' ends containing sequences from
the PEP4 gene and a URA3 gene. Because the ends of this
BglII fragment are homologous to adjacent sequences of
the PEP4 gene, integration of the fragment in the genome
of IGF-U was directed at the PEP4 locus via homologous
15 recombination that resulted in disruption of the PEP4
locus. The URA3 gene of the integrated DNA fragment
conferred a Ura⁺ phenotype on the transformants that
provided a marker for strains which were transformed.

Ura⁺ transformants were subsequently analyzed for
20 carboxypeptidase Y (CPY) activity using a colony overlay
calorimetric screening procedure (Jones, E. (1977)
Genetics 85: 23-33). Colonies which appeared to have low
carboxypeptidase Y (CPY) activity based on the results of
this assay were isolated, subcultured, and then
25 rescreened using the overlay assay. One of these strains
was designated M+IMB206S1.

3. Preparation of M+IGF816S1 and M+IGF816S4

Protease-deficient strains containing one or more
copies of the α MF-prepro-lys-arg-glu-ala-IGF-1 gene
30 expression cassette were generated by transformation of a
Pep4⁻ His4⁻ strain of P. pastoris, designated MGP21, with
pIGF816.

a. Generation of MGP21

The protease-deficient host strain MGP21 was
35 generated by gene replacement methods, as described in

-49-

U.S. Patent Application Serial No. 678,916, in which the PEP4 gene is replaced with a defective pep4 gene. Briefly, a His4⁻ Ura⁺ P. pastoris strain (GS4-2), selected from cells of a His4⁻ strain (GS115) that had been plated onto 5-FOA, was transformed with a linear fragment of a PEP4 disruption vector designated pDR602 (see U.S. Patent Application Serial No. 07/678,916). The linear fragment of pDR602 consisted of the P. pastoris URA3 gene flanked on each side with DNA coding for a portion of the P. pastoris PEP4 gene. Homology between the ends of the fragment and the endogenous PEP4 gene of GS4-2 stimulated integration of the fragment at the PEP4 locus resulting in a gene replacement event in which the defective URA3-containing pep4 gene replaced the endogenous PEP4 gene. The resulting strain, MGP21, is His4⁻ Ura⁺ Pep4⁻.

b. Transformation of MGP21

Strain MGP21 was transformed with StuI-digested pIGF816 via the lithium chloride method. Because StuI cleaves pIGF816 in the HIS4 gene, the linear fragment was directed to integrate into the his4 locus of strain MGP21. Resulting transformants were screened for histidine prototrophy. Two of the strains were designated M+IGF816S1 and M+IGF816S4.

4. Preparation of strain C+IGF816S1

A pep4 prb-1 IGF-1-expressing strain of P. pastoris containing one copy of the α MF prepro-lys-arg-glu-ala-IGF-1 expression cassette was generated by transformation of a pep4 prb-1 ura3 his4 P. pastoris host strain, designated MG18, with pIGF816.

a. Generation of MG18

Strain MG18 was generated by disruption of the PRB-1 gene of the pep4 ura3 his4 P. pastoris strain GS4-2521-4-5 (see U.S. Patent Application Serial No. 07/678,916 for a detailed description of the generation of GS4-2521-4-5 from the ura3 his4 strain GS4-2 via the intermediate

-50-

strain GS4-2521-4). This was accomplished by transformation of GS4-2521-4-5 with the PRB-1 disruption vector pDR911. Vector pDR911 (described in U.S. Patent Application Serial No. 678,916) contains an internal
5 portion of the *P. pastoris* PRB-1 gene, which, when used to transform PRB-1 strains of *P. pastoris*, integrates into the host genome at the PRB-1 locus to generate two incomplete and non-functional copies of the PRB-1 gene. Vector pDR911 also contains a complete functional *P.*
10 *pastoris* URA3 gene for use as a selectable marker in ura3 host strains of *P. pastoris*, such as GS4-2521-4-5.

Plasmid pDR911 was linearized by cleavage with BglII which cuts the plasmid within the fragment of the PRB-1 gene. The linear DNA was used to transform GS4-2521-4-5
15 according to the spheroplast method. Because the ends of this linear DNA are homologous to adjacent sequences of the PRB-1 gene, integration of the DNA into the genome of GS4-2521-4-5 was directed at the PRB-1 locus via a homologous recombination event resulting in the
20 disruption of the PRB-1 locus. The URA3 gene of the integrated DNA fragment conferred a Ura⁺ phenotype on the transformants that provided a marker for strains that had been transformed. Genomic DNA from transformants that were able to survive on media lacking uracil was analyzed
25 by Southern blot hybridization. The DNA was digested with EcoRV, separated by electrophoresis on a 0.75% agarose gel and transferred to nitrocellulose. The filter was probed with random-primed pDR911. The band pattern expected for a strain in which the PRB-1 gene had
30 been disrupted was a loss of the 5 kb fragment representing the endogenous undisrupted PRB-1 gene and the appearance of an approximately 10 kb fragment representing the endogenous 5 kb PRB-1 fragment plus the 5 kb linear vector DNA pDR911. DNA from 3 out of 40
35 transformants exhibited this band pattern. One of these

-51-

strains was MG18.

b. Transformation of MG18 with pIGF816

To develop pep4 prb-1 strains of P.

pastoris, strain MG18 was transformed with StuI-digested
5 pIGF816 by the lithium chloride method. Because StuI
cleaves pIGF816 in the HIS4 gene, the linear fragment was
directed to integrate into the his4 locus of strain MG18.
Resulting transformants were screened for histidine
prototrophy. One strain was designated C+IGF816S1.

A. One-Liter Fermentations

In order to maximize expression and secretion of IGF-1, the effects of glycerol concentration and pH on IGF-1 production in one-liter fermentations have been investigated.

1. Mut⁺ protocol: methanol fed-batch fermentation.

The Mut⁺ fermentation protocol included three separate phases: (1) cells are initially are cultured on glycerol in a batch mode; (2) following exhaustion of the glycerol, a limited glycerol feed is initiated such that glycerol does not accumulate, the AOX1 promoter is derepressed and cell mass increases: and (3) a methanol feed is initiated for production of heterologous protein in a methanol fed-batch mode.

Prior to use the fermentor was autoclaved with about one liter of medium containing 500 ml of 10x basal salts medium (final basal salts concentration of 5X, see above) and 30-50 g glycerol. After sterilization, 4 ml PTM, trace salts (see above) were added to the fermentor and the pH was adjusted to 5 with concentrated NH₄OH. In runs in which the pH was maintained at 5, pH was adjusted by addition of 50% NH₄OH containing 0.1% Struktol J673 antifoam. Dissolved oxygen was maintained above 20% of saturation by regulating agitation and aeration, or supplementing the air feed with oxygen. In low pH fermentations in which the pH was maintained between 2.8 and 3.5, the pH controller was adjusted to the desired pH either at the initiation of the limited glycerol feed or at the initiation of the methanol feed and then allowed to decrease by virtue of cellular metabolism to the desired pH.

Inocula were prepared from buffered YNB glycerol plates and grown overnight at 30°C in phosphate-buffered YNB (11.5 g/L KH₂PO₄, 2.66 g/L K₂HPO₄, 0.67% yeast nitrogen

-53-

base, pH 6)) containing 2% glycerol. The fermentor was inoculated with these cultured cells, which had grown to an OD₆₀₀ of 1-6, and the batch growth regimen was continued for 18 to 24 hours. At the point of glycerol exhaustion, indicated by increased dissolved oxygen, a glycerol feed (50% glycerol plus 12 ml/l of PTM₁) was initiated at a rate in the range of about 5-20 ml/h. This period of growth on limited glycerol was continued until a total volume of approximately 40-300 ml of feed was added to the fermentor. After addition of the glycerol feed, a methanol feed (100% methanol plus 12 ml/L PTM₁) was started. The initial rate of methanol addition was approximately 1-2 ml/h. The methanol feed rate was increased for 3 to 8 hours to 5-6 ml/h. In some fermentations the feed rate was directly increased to a rate of 6 ml/h after three hours of methanol feeding. The vessel was harvested 40-95 hours following initiation of methanol induction.

2. Mut⁻ protocol methanol fed-batch fermentation (Run 657).

The first two phases of the methanol fed-batch fermentations of the Mut⁻ strains were conducted as described for the Mut⁺ strain fermentations in Example 4(A)(1). However, the methanol induction phases of the Mut⁺ and Mut⁻ fermentation protocols differed in terms of the manner in which the methanol feeds were added to the cultures. In standard fermentations of the Mut⁻ strain, the methanol feed rate was adjusted to maintain an excess of methanol in the medium which did not exceed 0.3% (as determined by gas chromatography). The methanol feed was initiated at 1 ml/hr and after two hours was increased in 10% increments every 30 minutes to a rate of 3 ml/hr which was maintained for the duration of the fermentation. The vessel was then harvested after 101 hours of growth of the strain on methanol.

-54-

B. Ten-Liter Fermentations**1. Fed-batch**

a. Standard methanol feed rate (Runs 843, 959, 960, 962, 968 and 999).

5 A 15-liter fermentor containing 3.5 liters 10X basal salts and 220 g glycerol brought to a total volume of 5.5 liters by the addition of water was sterilized. After the fermentor had cooled, 24 ml PTM₁ trace salts were added and the pH was adjusted to 5.0 with the addition of
10 28% ammonium hydroxide. The pH of the fermentation was maintained by addition of the same solution and foaming was controlled with the addition of a 5% solution of Struktol J673. Temperature was maintained at 30°C, and dissolved oxygen was maintained above 20% of saturation
15 by regulating agitation, aeration, and reactor pressure or by supplementing the air feed with oxygen.

Inocula were prepared from cells grown overnight in buffered YNB (11.5 g/L KH₂PO₄, 2.66 g/l K₂HPO₄, 6.7 g/L yeast nitrogen base, pH 6) containing 2% glycerol. The
20 fermentor was inoculated with 500-700 ml of the cultured cells which had grown to a concentration of 2-8 OD₆₀₀, and the batch growth regimen was continued for 18-24 hours until glycerol was exhausted. At the point of glycerol exhaustion, indicated by an increase in dissolved oxygen,
25 a glycerol feed (50% w/v glycerol plus 12 ml/L PTM₁) was initiated at 100 ml/hr. After four hours, the glycerol feed was terminated and a methanol feed (100% methanol plus 12 ml/L PTM₁) was initiated at a rate of 20 ml/hr. After 304 hours of methanol feeding, the methanol feed
30 rate was increased to 60 ml/hr and maintained at this rate for the remainder of the fermentation. The vessel was harvested approximately 72 hours after the initiation of the methanol feed.

In pH 5 fermentations, the pH of the culture was
35 maintained at 5 throughout the fermentation. In low pH

-55-

fermentations (i.e., pH 2.8-3.0), the set point of the pH controller was adjusted to the target pH and the pH of the culture was allowed to decrease to the new set point as a result of cellular metabolism. In some

5 fermentations, the set point of the pH controller was adjusted at the initiation of the glycerol feed, whereas in other fermentations, the pH set point was not lowered until initiation of the methanol feed.

10 b. Modified methanol feed rates (Runs 789, 810 and 906).

Additional 10-liter fermentations were conducted essentially as described in Example 4.B.1.a. except with modified methanol feed rates. In Run 789, the methanol feed rate was steadily increased as the cell density
15 increased during the fermentation. After the initial three hours of methanol feeding at 20 ml/hr, the feed rate was increased to 30 ml/hr. The feed rate was then increased twice daily in proportion to the increase in cell mass.

20 In Run 810, the methanol feed rate was increased to 60 ml/hr after an initial four hours at 20 ml/hr. After 21 hours of methanol feeding, the feed rate was then increased to 100 ml/hr and maintained at the rate for the remainder of the fermentation (51 hours).

25 In Run 906, a methanol feed rate of 40 ml/hr was maintained for the first 60 hours of feeding, and then increased to 60 ml/hr for the remainder of the fermentation (90 hours total).

2. Continuous culture (Run 929).

30 In Run 929, the fermentation process was switched from a fed-batch to a continuous mode after 20 hours of methanol feeding. This was accomplished by initiating a 3X basal salts feed along with the methanol feed and maintaining a constant volume in the fermentor by
35 c ntinuous removal of whole broth (including cells). The

-56-

methanol feed was maintained at a constant rate of 70 ml/hr and the basal salts feed rate was set at 70% of the total feed (i.e., methanol plus basal salts) rate. Thus, a total feed of 230 ml/hr, containing 30% methanol, was fed into the fermentor with a constant total volume of 8 liters. Continuous culture was carried out for 139 hours (total of 159 hours on methanol).

C. Results

Samples (15-ml aliquots) of the fermentor culture were removed from the fermentor at various times throughout the course of the fermentation. Aliquots of each sample were centrifuged at 6500 x g for 5 min to separate broth and cells. The levels of the NH_4OH , antifoam, glycerol and methanol reservoirs were recorded at these time points. Methanol and ethanol concentrations in the supernatant were determined by gas chromatography using a PorapakQ column (Alltech, Deerfield, IL).

In addition, the wet weight of the culture was determined as an indicator of cell growth in the fermentor. For this purpose a one-ml aliquot of the fermentor culture was centrifuged for four minutes in a microfuge, the supernatant was decanted, and the wet pellet was weighed.

The IGF-1 levels of the cell-free broth were determined by RIA, quantitative immunoblot or reverse-phase HPLC (see Example 5 for a description of each of these methods). The results of fermentations of the IGF-1-expressing strains of *P. pastoris* are provided in the Tables I-V.

- * The pH was decreased from 5 to 2.8 at the initiation of the glycerol fed-batch phase.
- Continuous culture.
- Determined by Nichols RIA of cell-free broth (see Example 5A).
- Authentic IGF-1 levels determined by HPLC analysis of pretreated cell-free broth (see Example 5A).
- The pH was decreased from 5 to the indicated pH at the initiation of the methanol fed-batch phase.

As shown in Tables I- V, the four different assays used to measure IGF-1 levels yielded inconsistent results. As discussed in Example 5, the different assays most likely detect different combinations of the several species of IGF-1 present in varying concentrations in *P. pastoris* broth, including: intact correctly folded monomeric IGF-1, referred to as authentic IGF-1; multimeric IGF-1: nicked IGF-1; and incorrectly folded IGF-1; thereby providing differing values for IGF-1 concentrations of the broth. It is possible, however, to compare the IGF-1 levels of different fermentations when they are measured by the same assay. Such analyses yield the following conclusions.

-61-

The results of quantitative immunoblot analyses of fermentations of the six-copy strain G+IGF206S2 (Runs 576, 578, 596, 598 and 613) and the one-copy strain G+IGF201S1 (Runs 573 and 605) are shown in Table I. All samples quantified by immunoblot were first reduced with dithiothreitol (DTT), which disrupts disulfide bonds holding together multimeric or nicked IGF-1. Therefore, because only the protein that co-migrated with IGF-1 standard was quantified in this assay (see Example 5A), this method detected, but did not distinguish authentic monomer IGF-1, misfolded monomer IGF-1 and multimer IGF-1. The results shown in Table I demonstrate that expression cassette copy number has an effect on the level of immunoreactive IGF-1 contained in the broth, IGF-1 levels increase as the number of copies of the expression cassette contained in the strain increases (compare run 605 of the one-copy strain (21 mg/l) and Run 613 of the six-copy strain (489 mg/l)). A comparison of the IGF-1 levels of broth from fermentations conducted entirely at pH 5 (Runs 573 and 576) and the levels from fermentations conducted at lower pH (pH decreased from 5 to 3-3.5 at either initiation of glycerol feed (Runs 598, 605 and 613) or during methanol fed batch phase (Run 578)) reveals that the greatest amount of immunoreactive IGF-1 was obtained when the fermentation was conducted at lower pH. Furthermore, the time at which the pH was lowered from 5 to ≤ 3.5 also had an effect on IGF-1 levels. Lower IGF-1 levels were obtained when the pH of the fermentation was decreased later in the fermentation, i.e., during the methanol fed batch phase (compare Runs 598 and 578). The results of several fermentations of the six-copy strain conducted according to the same protocol (addition of 150 g of glycerol, 60-70 hours of methanol feeding, and decrease in pH from 5 to 3 at the initiation of glycerol feeding) demonstrated the

-62-

reproducibility of the IGF-1 production process, since all fermentations typically yielded between approximately 350-480 mg/l).

The results of Incstar antisera-based RIAs (Table II; see Example 5A for a description of this assay) of broth from fermentations of the six-copy strain G+IMB206S1 (Run 661), the four-copy strain G+IMB204S14 (Run 691), the two-copy strain G+IMB202S2 (Run 680) and the one-copy strain G+IGF201S1 (Run 605) further illustrate the dramatic effect of expression cassette copy number on IGF-1 expression by *P. pastoris*. The four- and six-copy strains produced similar levels of RIA-reactive IGF-1 (1400 and 1280 mg/l, respectively) and 2- and nearly 10-fold more IGF-1 than the two- and one-copy strains (740 and 167 mg/l, respectively). Furthermore, the Mut⁺ six-copy strain G+IMB206S1 appeared to be superior to the Mut⁻ six-copy strain (G-IMB206S3) in terms of IGF-1 production capability (compare Runs 661 and 657). Incstar antisera-based RIAs of broth from Runs 661 and 694 (strain G+IMB206S1) were in agreement with the finding that pH 5 fermentations yield significantly lower levels of IGF-1 than low pH fermentations.

Although Nichols RIAs consistently yielded lower values for IGF-1 expression levels than the Incstar antisera-based RIA, the relative IGF-1 levels from different fermentations, as measured by Nichols RIA, were in agreement with those as measured by Incstar antisera-based RIAs. For instance, a comparison of the IGF-1 levels of fermentations of the two-, four-, and six-copy strains G+IMB202S2 (Run 680), G+IMB204S14 (Run 691) and G+IMB206S1 (Run 661), respectively, as determined by Nichols RIA, further demonstrated the effect of expression cassette copy number on IGF-1 expression levels. Furthermore, the level of IGF-1 product determined by Nichols RIA was significantly higher in

-63-

fermentations conducted at lower pH: compare Run 694 (pH 5; 15 mg/l) and Run 661 (pH 3; 140 mg/l) and Run 776 (pH 2.8; 355 mg/l). Finally, it appears that changing the amount of glycerol added during the glycerol batch and fed batch phases had little effect on the final IGF-1 concentration from fermentations of the four-and six-copy strains (compare Runs 772 (85 g glycerol added) and 776 (45 g glycerol added) which both produced approximately 345 mg/l; also compare Runs 756, 756, 757, 773 and 775 (glycerol added carried from 40-175 g) which yielded 250-300 mg/l).

HPLC analysis (see Example 5C) of fermentation broth permitted distinction and accurate measurement of each species of IGF-1 present in the broth. Table IV lists the levels of authentic IGF-1, as determined by reverse-phase HPLC of broth from one-liter fermentations of IGF-1-expressing strains of *P. pastoris*. The results of these HPLC analyses are consistent with those of RIA and immunoblot analyses of broth in terms of the relative IGF-1 levels in broth from different strains grown under different conditions. As shown in Table IV, expression cassette copy number clearly influences IGF-1 expression levels (compare IGF-1 levels of broth from a one-copy strain, G+IGF201S1 (14 mg/l, Run 605), a two-copy strain, G+IMB202S2 (39 mg/l, Run 680), a four-copy strain, G+IMB204S14 (101 mg/l, Run 691) and a six-copy strain, G+IMB206S1 (121 mg/l, Run 772)). In addition, the results in Table IV demonstrate the effect of pH on production of IGF-1 in *P. pastoris*; fermentations of strains G+IMB206S1 and G+IMB204S14 conducted at pH 5 (Runs 694 and 943, respectively) yielded essentially no authentic IGF-1 (or any form of IGF-1); whereas 121 and 74 mg of IGF-1/l were produced in low pH fermentations of these strains (Runs 772 and 757, respectively, pH was decreased from 5 to 2.8 at the initiation of the glycerol fed batch phase). Th

-64-

results of HPLC analysis of broth from several different low pH fermentations of strain G+IMB204S14 in which the amount of glycerol added to the fermentor varied between 40 and 175 g confirmed the finding that differing
5 glycerol levels in this range had no effect on IGF-1 production; all fermentations yielded 70-110 mg/l.

The broth from one-liter fermentations of the protease-deficient (pep4) strain M+IMB206S1 was also analyzed by HPLC. As shown in Table IV, pH 5 and low pH
10 fermentations (Runs 935 and 934, respectively) of this strain yielded similar high levels (167 and 139 mg/l, respectively) of authentic IGF-1. Furthermore, the level of authentic IGF-1 produced in these fermentations of
15 strain M+IMB206S1 was approximately 60% higher than that produced in pH 2.8 fermentations of the four-copy strain PEP4 G+IMB204S14 (Run 757; 74 mg/l) and approximately 15% higher than that produced in pH 2.8 fermentations of the six-copy PEP4 strain G+IMB206S1 (Run 772; 121 mg/l).

The results of HPLC analysis of broth from one-liter
20 fermentations of strains containing one or more α MF prepro-lys-arg-glu-ala-IGF-1 expression cassettes are also shown in Table IV. These strains showed two different levels of IGF-1 expression. Strains G+IGF816S1 and G+IGF816S2 yielded similar levels of authentic IGF-1
25 (approximately 16 mg/l) in two identical fermentations (Runs 1039 and 1048). In contrast, strains G+IGF816S9 and G+IGF816S11 produced three-fold more authentic IGF-1 (approximately 45 mg/l) in Runs 1049 and 1050. Therefore, it appears that strains G+IGF816S9 and
30 G+IGF816S11 fortuitously incorporated 2-3 copies of the α MF prepro-lys-arg-glu-ala-IGF-1 expression cassette into their genomes; whereas strains G+IGF816S1 and G+IGF816S2 apparently contain a single copy of the expression cassette.

35 Broth from fermentations of protease-deficient

-65-

strains M+IGF816S1 (pep4), M+IGF816S4 (pep4) and C+IGF816S1 (pep4 prb-1) containing one or more α MF prepro-lys-arg-glu-ala-IGF-1 expression cassettes (see Example 2C) also was analyzed by HPLC. Based on the authentic IGF-1 levels of the broth from low pH fermentations of strains M+IGF816S1 and C+IGF816S1 (Runs 1047 and 1055, 16-20 mg/l) as compared to those of the broth from low pH fermentations of strain M+IGF816S4 (Run 1053, 33 mg/l), it appears that strains M+IGF816S1 and C+IGF816S1 contain one copy of the expression cassette; whereas M+IGF816S4 contains two or more expression cassettes. It is noteworthy that pH 5 fermentations of these strains (Runs 1066 and 1067) yielded at least as much authentic IGF-1 as low pH fermentations of these strains. In contrast, pH 5 fermentations of a PEP4 strain containing multiple copies of the α MF-lys-arg-glu-ala-IGF-1 expression cassette (Run 1069) yielded no authentic IGF-1.

As shown in Table V, high-level production of IGF-1 by P. pastoris was readily scaled up to the 10-liter fermentation level. A comparison of low pH 10-liter fermentations of the four-copy strain G+IMB204S14 conducted with varying methanol feed rates (Runs 789, 810, 843, and 906) revealed similar levels of authentic IGF-1 production. A significant level of authentic IGF-1 (54 mg/l) was produced in a pH 5.0 10-liter fermentation of the pep4 strain M+IMB206S1 (Run 959). This level was increased in 10-liter fermentations of this strain that were initiated at pH 5 and then conducted at pH 2.8 or 3.0 during the entire methanol fed batch phase (Runs 960 and 999, respectively). A similar fermentation of strain G+IMB204S14 (Run 962) yielded IGF-1 levels equivalent to those obtained in a fermentation in which the initial pH of 5 was decreased to 2.8 upon initiation of the glycerol fed batch phase (Runs 789, 810, 843 and 906). Continuous

-66-

culture of strain G+IMB204S14 (Run 929) produced between 55 and 70 mg/l of authentic IGF-1 at a rate of 230 ml of culture media per hour. Therefore, the productivity of continuous culture fermentations was slightly higher than that of fed-batch fermentations.

EXAMPLE 5

MEASUREMENT OF IGF-1 CONCENTRATIONS IN THE CULTURE MEDIUM.

A. RIA Assay.

A 1:5000 final dilution of rabbit anti-human IGF-1 antisera (Incstar anti-somatomedin C antibody, catalog #22275), 10,000-12,000 cpm of ¹²⁵I-IGF-1 (Incstar catalog #22303), and various dilutions of recombinant human IGF-1 standard (purchased from Incera and quantified by amino acid analysis) or the unknown broth solution were incubated overnight at 4°C in a final volume of 0.5 ml in 12 x 75 mm polystyrene tubes. At the end of the incubation, 100 µl of Pansorbin (working dilution of 1:40) was added to the tubes and incubated for 15 minutes at room temperature. Two milliliters of RIA buffer (50 mM NaPO₄, 0.1% BSA, 0.1% NaN₃, and 0.1% Triton X-100, pH 7.4) were added to each tube before centrifugation at 3200 rpm for 68 minutes at 4°C in a Beckman J6M centrifuge. Following centrifugation, the supernatant was decanted and the radioactivity associated with the pelleted material was determined in a gamma counter.

Alternatively, some of the samples were assayed using a commercial RIA (Nichols Institute Diagnostic; San Juan Capistrano, CA). The Nichols assay consistently measured lower levels for IGF-1 than the RIA described above (see data above from Runs 661, 680, 691 and 694). This apparent discrepancy probably arises because the antibody used in the RIA described above detects both monomer and multimer IGF-1, whereas the antibody used in the Nichols assay most likely detects monomer IGF-1 only.

-67-

B. Western blot

Immunoblot analysis of P. pastoris fermentation broth was used to qualitatively and quantitatively evaluate IGF-1 production in P. pastoris.

- 5 Several dilutions of recombinant human IGF-1 standard (Imcera) and samples of cell-free broth obtained at the conclusion of selected fermentations of the Mut⁺ and Mut⁻ IGF-1-expressing strains of *Pichia pastoris* were analyzed by quantitative western blots to estimate the
- 10 amount of immuno-reactive IGF-1 contained in the broth. The proteins were first separated by Tricine SDS-PAGE (Schegger, H. and von Jagow, G. (1987) Anal. Biochem. 117: 304-310) and then transferred to 0.1 μ m nitrocellulose by electroblot in a solution of Towbin
- 15 buffer (25 mM Tris-HCl, pH 8.3, 190 mM glycine, 20% methanol) for at least 90 minutes at 20 V/cm. After the proteins were transferred onto nitrocellulose, the filter was incubated for one hour in blocking buffer (0.25% gelatin, phosphate-buffered saline, 0.05% Tween 20, 0.02%
- 20 sodium azide). Rabbit anti-IGF-1 antisera 10A was diluted 1:2000 with blocking buffer and incubated with the filter for a minimum of two hours. Antibody 10A was raised against a synthetic peptide corresponding to the last 14 amino acids of the carboxy terminus of human IGF-
- 25 1, which was conjugated to human α -globulin. The antisera was adsorbed to α -globulin prior to use. The filter was washed with blocking buffer for an hour and incubated with ¹²⁵I-Protein A (0.02 μ Ci/ml) for 45 minutes. After one hour of washing with blocking buffer,
- 30 the filter was air dried and exposed to X-ray film with an intensifying screen at -75°C. To estimate the IGF-1 content of broth, the intensities of bands corresponding to IGF-1 in lanes containing broth were compared to the intensities of bands corresponding to different known
- 35 amounts of IGF-1 standard. Autoradiographs were used as

-68-

templates and the portions of the gels corresponding to bands were excised and the radioactivity in the bands counted in a scintillation counter. A standard curve was prepared by plotting the cpm of bands containing known amounts of IGF-1 versus IGF-1 concentration was prepared and the IGF-1 content of the broth was estimated by comparison with the standard curve.

C. Quantitative Reverse-Phase High-Performance Liquid Chromatography (HPLC)

1. HPLC System

A Waters (Bedford, MA) 600 solvent delivery system, Waters Model 481 Lambda Max variable wavelength detector, Wisp 710B auto-injector and a Shimadzu Crom-Pac integrator (Cole Scientific, Moorepark, CA) constituted the HPLC system. A Vydac C4 column (0.46 X 5 cm) with a guard column was used to resolve components of the Pichia pastoris-produced IGF-1 preparations. Broth samples that had been pretreated as described in Example 6.C.2. below were loaded onto the column at a flow rate of 1 ml/minute and were eluted in a trifluoroacetic acid (TFA)/acetonitrile-TFA gradient. The eluant was prepared by using mobile phase A (0.1% TFA) to dilute mobile phase B (95% acetonitrile, 5% water, 0.1% TFA). A 1%/minute gradient of 25% to 42% mobile phase B was passed through the column during a period of 17 minutes at a flow rate of 1 ml/minute to elute the material that had been loaded onto the column. The column was then regenerated with 100% mobile phase B at a flow rate of 2 ml/minute for 4 minutes followed by 25% mobile phase B for 4 minutes at 2 ml/minute. The flow rate was then reduced to 1 ml/minute and the column was equilibrated at the initial starting conditions (25% mobile phase B) for 2 minutes before

-69-

reinjection with another sample to be analyzed. The detector was set at 0.05 absorbance units full scale (AUPS) and a wavelength of 215 nm was used for maximum sensitivity.

5 2. Pretreatment of crude fermentation broth.

P. Pastoris-produced IGF-1 exists as several forms in the broth of fermentations of IGF-1-expressing P. pastoris strains. HPLC analysis of crude cell-free broth from fermentations of IGF-1-expressing P. pastoris does
10 not adequately resolve the various IGF-1 species. In order to distinguish these IGF-1 species by HPLC, the authentic P. pastoris proteins must be removed from the broth by a small-scale cation exchange chromatography step. Several cation exchange systems were tested for
15 this purpose: sulfylpropyl cation exchange capsules (FMC (Pinebrook, NJ) and Cuno (Meriden, CT)) and the use of a bulk cation exchanger (e.g., S-Sepharose Fast Flow (Pharmacia, Uppsala, Sweden), SP-Spherox (IBF, Columbia, MD), or Toyopearl SP650M and SP550C (Toso
20 Haas, Woburn, MA)) in a 2-ml disposable polypropylene column (0.8 x 4 cm, BioRad) with an integrated 10-ml reservoir. Any of these systems yielded satisfactory results. The two systems routinely used to pretreat crude broth for quantitative HPLC analysis of the IGF-1 levels
25 employed the Cuno cation exchange capsule or the SP-Spherox or SP550C cation exchangers in a column format. The crude broth was cleaned up by cation exchange chromatography and injected directly onto an HPLC column. The resulting chromatogram clearly resolved the different
30 IGF-1 species in broth.

 a. Pretreatment using cation exchange capsules.

 The Cuno cation exchange capsule is a 25-mm disk. It was first washed with a 4 ml 0.2 M acetic acid, then

-70-

equilibrated with 4 ml 0.02 M acetic acid. A volume of crude broth (1-10 ml) was diluted 1:2 with 0.02 M acetic acid. A volume of crude broth (1-10 ml) was diluted 1:2 with 0.02 M acetic acid and loaded onto the disk. After
5 loading, the disk was washed with 1.5 ml 0.02 M acetic acid and the IGF-1 was eluted with 4 ml 0.02 M sodium acetate, Ph 5.5, plus 1 M NaCl. The first 1.5 ml of eluate contained 75-80% of the total IGF-1 and was usually the only elution volume collected. The capsule
10 could then be regenerated by washing with 4 ml of 100% methanol.

b. Pre-treatment using bulk cation exchanger in a column format.

To the disposable column, 0.25 ml of
15 prehydrated cation exchanger was added. The absorbent was first washed with 2 ml of 0.2 M acetic acid, then equilibrated with 2 ml of 0.02 M acetic acid. A volume of broth (1 ml) was loaded onto the column which was then washed with 1 ml of 0.02 M acetic acid. All buffers and
20 broth were carefully added to the column in an effort to avoid disruption of the column bed. Although some suspension of the absorbent usually occurred during addition of liquid to the column, it was not detrimental to sample binding or eluting. Broth samples and buffer
25 were allowed to flow through the column by gravity. The IGF-1 was eluted with 2 ml of a 0.05% M sodium acetate, pH 5.5, buffer containing 1 M NaCl. The first milliliter of eluate contained 80-90% of the total IGF-1, eluted by the 2 ml of elution buffer. Periodically (approximately
30 every 5-10 samples), the column was regenerated after the salt elution with a 50% methanol wash. Less often, the column was also regenerated with 0.5 M NaOH. These

-71-

columns retain their selective binding properties through many successive uses.

3. Measurements of IGF-1 concentrations.

In order to measure the concentrations of Pichia-produced IGF-1 by HPLC, known amounts of standard IGF-1 (Amgen, Thousand Oaks, CA) and authentic Pichia-produced IGF-1, which was purified as described in U.S. Patent Application Serial No. 07/641,430) and quantified by amino acid composition analysis were injected onto the HPLC column and the area under the corresponding peaks in the chromatogram was measured. A standard curve was generated by plotting area versus micrograms of IGF-1 loaded onto the HPLC column. A conversion factor for use in converting the area under HPLC chromatogram peaks to IGF-1 concentration was calculated from the standard curve. Using this information, it was possible to determine the concentration of authentic IGF-1 in a pretreated broth sample by measuring the area under the corresponding peak on the chromatogram from HPLC analysis of the sample. This conversion factor was also used to estimate the approximate concentration of other IGF-1 species as well. The absolute concentrations of each of these other species, however, may vary depending on differences in their specific conversion factors.

25

EXAMPLE 6

CHARACTERIZATION OF THE IGF-1 SECRETED INTO THE CULTURE MEDIUM

Pichia-produced IGF-1 was characterized by immunoblot, SDS-PAGE, HPLC, and protein sequence analyses. These methods and the results of these analyses are described in this example.

30

A. Immunoblot Analysis

Several characteristics of the IGF-1 produced in fermentations of IGF-1-expressing P. pastoris were

-72-

ascertained from immunoblot analysis of reduced (by adding dithiothreitol (DTT)) and non-reduced (no added DTT) samples of broth (performed as described in Example 5B).

5 First, if the broth samples were not reduced prior to electrophoresis, the IGF-1 migrated as several forms which appeared to be a monomer, dimer and various multimers of IGF-1. The ratio or profile of monomer to multimer forms of secreted IGF-1 did not seem to be
10 affected by copy number. Second, the immunoblot of reduced samples revealed the absence of most of the higher molecular weight immunoreactive species that were evident in the nonreduced broth samples, and revealed the presence of a protein that co-migrates with IGF-1
15 standard (monomer) as well as immunoreactive protein which migrates to a position slightly below that of standard IGF-1. N-terminal protein sequence analysis (Example 6.d.) of this lower molecular weight immunoreactive species demonstrated that it begins with
20 residue 25 of mature human IGF-1 and, thus, is a proteolytic fragment of IGF-1. Since this lower molecular weight species is not seen under non-reducing conditions, the IGF-1 molecule may be nicked only between residues 24 and 25, i.e., not completely fragmented, with
25 the disulfide bonds at Cys-6/Cys-48 and Cys-18/Cys-61 of IGF-1 holding the peptide fragments that contain amino acids 1-24 and 25-70 together. Further, the decreased glycerol fermentation (Run 755) produced wholly intact IGF-1 molecules (no degradation), while the extended
30 glycerol feed fermentation (Run 756) demonstrated a low level of degraded product. The degradation appeared to be slightly higher with the six-copy strain (Run 776) than with the four-copy strain (Run 775).

-73-

IGF-1 produced in the fermentation of the six-copy Mut⁻ strain (Run 657) was also analyzed by SDS-PAGE and Western blot. The IGF-1 band patterns of reduced and non-reduced broth from the fermentation of the six-copy Mut⁻ strain are similar to the band patterns of reduced and non-reduced broth from the fermentations of the six-copy and four-copy Mut⁺ strains.

B. Qualitative HPLC Analysis

Crude P. pastoris fermentation broth was also analyzed by HPLC (see Example 5.C.1 for a description of the HPLC system used in this analysis). Direct injection of crude broth onto the HPLC column did not result in a chromatogram with distinct peaks. In order to analyze the components of crude broth by HPLC, it was necessary to remove endogenous P. pastoris contaminants from the broth using small-scale cation exchange chromatography, as described in Example 5.C.

The eluate obtained after small-scale cation exchange chromatography of cell-free broth from a low pH fermentation of an IGF-1-expressing strain of P. pastoris contains all the IGF-1 polymers, including nicked, misfolded, multimeric and authentic IGF-1 which can be resolved by the HPLC protocol described in Example 5C. The different peaks detected in the chromatogram from HPLC analysis of broth that had been subjected to cation exchange chromatography correspond to different forms of IGF-1 produced in recombinant P. pastoris fermentations. The identity of the proteins corresponding to these peaks was established in HPLC, SDS-PAGE, immunoblots, gel filtration, cation exchange and hydrophobic interaction chromatography (performed as described in US Patent Application Serial No. 641,430).

A chromatogram from HPLC analysis (conducted as described in Example 5C.) of broth from a fermentation of an IGF-1-expressing P. pastoris strain contains a peak

-74-

corresponding to protein that eluted from the HPLC column at approximately 10 minutes, which represents correctly folded, intact IGF-1 monomer. The identity of this protein was confirmed initially on the basis of its
5 elution time by HPLC, which is identical to that of standard recombinant IGF-1 (Amgen, Thousand Oaks, CA). Furthermore, the protein with an elution time of approximately 10 minutes was purified (see U.S. Patent Application Serial No. 641,430) and subjected to
10 additional analyses. SDS-PAGE analysis of reduced and non-reduced samples of the purified protein yielded identical results, revealing that it was a 7.7-kDa intact protein that co-migrated with IGF-1 standard. Immunoblot analysis of the purified protein demonstrated that it is
15 reactive with an antibody generated against the last 14 amino acids of IGF-1. Gel filtration chromatography of the purified protein revealed that it elutes as expected for an IGF-1 monomer of the correct size. Finally, amino acid analysis confirmed that the amino acid ratios of the
20 purified protein correspond to those of standard IF-1. Protein sequence analysis showed that the complete amino acid sequence of the purified protein is identical to that of authentic IGF-1.

The protein that elutes from the HPLC column at
25 approximately 8.6 minutes was tentatively identified as misfolded IGF-1. This protein was isolated by HPLC and hydrophobic interaction chromatography and characterized by SDS-PAGE, immunoblot and protein sequence analysis. SDS-PAGE analysis of reduced and non-reduced samples of
30 this protein demonstrated that this form migrated with authentic monomeric IGF-1 and that it was not a nicked form of IGF-1. Immunoblot analysis of this protein using an antibody directed against the C-terminus of IGF-1

-75-

showed that it was immunoreactive. Amino-terminal protein sequencing of this protein also confirmed that the molecule was intact since only one amino-terminal sequence could be identified. These results suggest that
5 this form is a misfolded species of IGF-1.

The proteins that elute from an HPLC column at 10.5-11.5 minutes were identified as nicked or degraded forms of IGF-1 (i.e., IGF-1 molecules containing two or more peptide fragments, generated by cleavage of one or more
10 peptide bonds and held together by disulfide bonds). There appears to be at least two peaks by HPLC analysis of cleaned up broth that correspond to the nicked IGF-1. The protein represented by the major peak (eluting at 10.7 minutes) was isolated during the S-Sepharose cation
15 exchange step of the IGF-1 purification process (see U.S. Patent Application Serial No. 641,430). SDS-PAGE analysis of non-reduced samples of this isolated species revealed that it co-migrated with IGF-1 standard and appeared as a single band. Gels of reduced samples of
20 this protein, however, exhibited a doublet representing two peptides of approximately 3-4 kDa each (approximately half the size of intact IGF-1). The position of this doublet in the gel corresponded to that of the lower of the two bands detected below the band representing intact
25 IGF-1 in gels of reduced samples of crude broth. These results indicate that this molecule is monomeric IGF-1 cleaved or nicked and held together by disulfide bonds. Amino-terminal protein sequence analysis of the protein confirmed that the molecule is nicked prior to residue 40
30 of IGF-1. Immunoblot analysis of reduced and non-reduced samples of this isolated nicked IGF-1 molecule revealed that it is less reactive than intact IGF-1 with the antibody directed against the C-terminus of IGF-1.

Two additional nicked species were identified in
35 protein sequence analysis of IGF-1 recovered from the

-76-

first cation exchange chromatography step of the purification process (see U.S. Patent Application Serial No. 641,430). Either or both of these species could correspond to the minor peak in the HPLC chromatogram of cleaned up cell-free broth (protein eluting at 11 minutes). The amino-terminus of the C-terminal fragment of one of these nicked molecules begins at residue 25 of IGF-1. The amino terminus of the C-terminal fragment of the other nicked species detected in the broth begins at residue 14 of IGF-1.

The last set of proteins detected in HPLC analysis of cell-free broth, which elute from the HPLC column after 11.5-16 minutes, appears to be disulfide-bonded multimer forms of IGF-1. The presence of disulfide-bonded IGF-1 multimers in *P. pastoris* broth was indicated in SDS-PAGE gels of broth and immunoblots of the gels. The putative multimers migrated as IGF-1 dimers and trimers on non-reduced SDS-PAGE gels and were reactive with antibody directed against the C-terminus of IGF-1. When these multimers were reduced, they co-migrated with standard monomer IGF-1 in SDS-PAGE gels, which indicates that contain disulfide-bonded IGF-1 monomers. The amino acid sequence generated in protein sequence analysis of gel-isolated dimer was identical to the N-terminus of authentic IGF-1. Furthermore, multimer IGF-1 (apparent dimer and trimer species) were isolated on a gel filtration column and analyzed by HPLC. The isolated multimer eluted from the column at 12-14 minutes, which corresponds to the elution times of the proteins in broth that were proposed to be multimers of IGF-1.

EXAMPLE 7

CHARACTERIZATION OF PURIFIED AUTHENTIC PICHIA-PRODUCED IGF-1.

Correctly folded, intact, monomeric IGF-1 (authentic IGF-1) was purified from the broth of IGF-1-expressing

-77-

strains G+IMB204S14 and M+IMB206S1 using a combination of cation exchange chromatography, hydrophobic interaction chromatography and gel filtration chromatography methods. The purification procedure is described in detail in U.S.

- 5 Patent Application Serial No. 07/641,430. The purified material was characterized by HPLC, gel filtration chromatography, SDS-PAGE and immunoblot analysis, and amino acid composition and sequence analysis.

A. HPLC Analysis

- 10 Several different dilutions of the purified preparation were subjected to HPLC using the system and procedure described in Example 5C. A single major peak was detected in the resulting chromatogram which represented a protein with an elution time identical to
- 15 that of IGF-1 standard.

B. Gel Filtration Chromatography

1. Procedure

- A Superdex 75 HR 10/30 gel filtration column (Pharmacia) with a bed volume of 24 ml (10 x 300 mm) was
- 20 used in gel filtration chromatography methods of characterizing IGF-1 on the basis of size. The HPLC system described in Example 5C was modified for use with this column. The detector was set at a wavelength of 280 nm and a sensitivity of 0.02 AUFS. The gel filtration
- 25 chromatography column buffer contained 0.05 M ammonium acetate, pH 6. Buffer was flowed through the column at a flow rate of 0.5 ml/minute.

2. Results

- The chromatogram from gel filtration chromatography
- 30 analysis of 200 µg of purified IGF-1 yielded a single peak representing protein that co-eluted with IGF-1 standard.

C. SDS-PAGE and Immunoblot Analysis.

- The purified material was examined by SDS-PAGE and
- 35 immunoblot methods as described in Example 5B. Only a

-78-

single band was detected in both silver-stained gels and immunoblots of reduced and non-reduced samples of the material containing 1 μ g of protein or less. This protein co-migrated with IGF-1 standard.

5 D. Amino Acid Composition

Purified IGF-1 was acid hydrolyzed, and the amino acids were characterized on a Beckman (Palo Alto, CA) 6300 Amino Acid Analyzer. To acid hydrolyze the IGF-1 protein, carefully measured volumes of purified IGF-1 solution were added to 6 x 50 mm glass tubes and dried in a Savant (Farmingdale, NY) Speed Vac. These tubes were placed in a reaction flask containing 0.5 ml 6 N HCl. Oxidation was minimized by applying a vacuum and sealing the flask. The flask was placed overnight in a 110°C oven, and the protein was hydrolyzed by the HCl vapors.

Following hydrolysis, the reaction flask was cooled to room temperature, and the hydrolyzate was removed. Any HCl that may have condensed in the tubes was removed by drying the tubes in a Speed Vac. The free amino acids were dissolved in a minimum of 100 μ l Beckman Amino Acid Sample Dilution Buffer, Na-S, for loading in the 50- μ l loop of the analyzer. A Nelson (Cupertino, CA) 3000 Series Chromatography Data System was used to measure concentrations by comparing the integrated chromatogram of amino acid standard solutions and of the resuspended, hydrolyzed sample.

Table VI shows the amino acid ratios estimated for the purified IGF-1 and the actual published amino acid ratios for human IGF-1. The estimated and published ratios are in close agreement, and slight deviations in the estimated and published compositions are within the expected limits of this analysis.

-79-

30 E. Amino Acid Sequence

1. Procedure

To determine the N-terminal amino acid sequence of the IGF-1 purified from the broth of strain M+IMB206S1, samples of this material were loaded directly onto an
35 Applied Biosystems (Foster City, CA_ 470/120 Gas Phase Protein Sequencer. Sequencing was performed according to the methods described by Hunkapiller and Hood (*Science* 215:650 (1983)).

To determine the entire amino acid sequence of IGF-1
40 purified from the broth of strain G+IMB204S14, the material was sequenced from the N-terminal amino acid through as much of the remainder of the protein sequence as possible. This analysis generated the sequence of the first 59 residues of the purified protein. Because the

-80-

amino acid at residue 59 is a methionine residue, and cyanogen bromide cleaves proteins after methionine residues, it was possible to isolate the peptide containing the C-terminal 11 amino acids (residues 60-70) of purified IGF-1 for use in completing the protein sequence analysis of the purified material. The C-terminal 11 amino acids of the purified IGF-1 were obtained as a peptide fragment isolated from cyanogen bromide-treated IGF-1 by HPLC, using the same C4 column as described in Example 5C. This fragment was loaded onto the protein sequencer to generate the sequence of the C-terminal amino acids (amino acids 60-70).

The N-terminal amino acid sequences of authentic IGF-1 from the broth of fermentations of strains G+IGF816S1 and G+IGF816S11 were also determined. The broth was pre-treated as described in Example 5C and subjected to HPLC (also as described in Example 5C). The fraction that eluted from the HPLC column with an elution time identical to that of standard IGF-1 was applied to an SP-Spheredex column to remove the HPLC solvent (acetonitrile and TFA). The eluate fraction containing the IGF-1 was then loaded directly onto the protein sequencer.

2. Results

The first 30 amino acids of the IGF-1 purified from the broth of strain M+IMB206S1 and the entire amino acid sequence of IGF-1 purified from broth of strain G+IMB204S14 were identical to the corresponding amino acids of human IGF-1, Sequence ID No. 1.

Similarly, the first 15 amino acids of the IGF-1 from the broth of strains G+IGF816S1 and G+IGF816S11 were identical to the corresponding amino acids of human IGF-1. These results confirm that mature IGF-1 is correctly processed from the α MF prepro-lys-arg-IGF-1 or α MF prepro-lys-arg-glu-ala-IGF-1 precursor in *P. pastoris*.

-81-

Since modifications will be apparent to those of skill in the art, it is intended that this invention be limited only by the scope of the appended claims.

-86-

THAT WHICH IS CLAIMED IS:

1. A DNA construct, comprising:
 - (a) DNA encoding an insulin-like growth factor-1 (IGF-1);
 - 5 (b) a promoter region from a methanol responsive gene of a methylotrophic yeast operably linked to said DNA that encodes IGF-1;
 - (c) DNA encoding a signal sequence of amino acids that effect extracellular secretion of IGF-1 from a
10 methylotrophic yeast host cell,
wherein the DNA that encodes said signal sequence is operably linked via DNA encoding one or more processing sites that are recognized and cleaved by methylotrophic yeast cell proteases to the DNA that encodes IGF-1.
- 15 2. A methylotrophic yeast host cell, comprising the DNA construct of claim 1, wherein said DNA construct is into the genome of said host cell.
3. A process for producing IGF-1, comprising culturing the yeast host cell of claim 2 under conditions
20 whereby IGF-1 is expressed and secreted into extracellular medium at concentrations of 10 mg/ml or greater.
4. A DNA construct, comprising an expression cassette that contains:
 - 25 (a) DNA encoding an insulin-like growth factor-1 (IGF-1);
 - (b) a promoter region from a methanol responsive gene of a methylotrophic yeast operably linked to said DNA that encodes IGF-1;
 - 30 (c) DNA encoding the S. cerevisiae α -mating factor (α MF) pre-pro sequence;
 - (d) a transcription terminator functional in a methylotrophic yeast host cell operably linked to said DNA that encodes IGF-1,
35 wherein the DNA that encodes said pre-pr sequence

-87-

is operably linked via DNA encoding one or more processing sites selected from the group consisting of lys-arg and lys-arg-(glu-ala)_x to the DNA that encodes IGF-1;

5 x is the number of repeats of glu-ala sequences and is less than the number of repeats that results in improperly cleaved IGF-1 in the extracellular medium.

5. The DNA construct of claim 4, wherein x is 1, 2 or 3.

10 6. A DNA construct of claim 4, further comprising at least one selectable marker gene and a bacterial origin of replication.

7. A plasmid comprising the DNA construct of claim 6.

15 8. The plasmid of claim 7, selected from the group consisting of pIGF201, pIGF202, pIGF204, pIGF206 and pIGF816.

9. The DNA construct of claim 4, wherein said the DNA encoding an IGF-1 peptide has the sequence set forth
20 in Figure 1.

10. The DNA construct of claim 4, wherein said methylotrophic yeast from which the promoter is derived is a strain of Pichia pastoris.

25 11. The DNA construct of claim 10, wherein said methanol-responsive gene of a methylotrophic yeast and the transcription terminator are both derived from the P. pastoris AOX1 gene.

12. The DNA construct of claim 11, wherein the 3'- and 5'-ends of the construct have sufficient homology
30 with a target gene of a yeast host to effect site directed integration of said construct into said target gene.

13. A DNA construct of claim 12, comprising multiple copies of said expression cassette.

35 14. A DNA construct of claim 4, wherein the 3'- and

-88-

5'-ends of the construct have sufficient homology with a target gene of a yeast host to effect site directed integration of said construct into said target gene.

15 15. A DNA construct of claim 4, comprising multiple copies of said expression cassette.

16. The DNA construct of claim 15, wherein said multiple copies of said expression cassette are oriented in head-to-tail orientation.

10 17. A DNA construct of claim 4, wherein said construct is included in the DNA in plasmids selected from the group consisting of pIGF201, pIGF202, pIGF204, pIGF206 and pIGF816.

18. A methylotrophic yeast cell, comprising the DNA construct of claim 4.

15 19. A methylotrophic yeast cell, comprising the DNA construct of claim 9.

20. The methylotrophic yeast cell of claim 18, wherein said yeast is a strain of Pichia pastoris.

20 21. A methylotrophic yeast cell, comprising the DNA construct of claim 15.

22. A Pichia pastoris cell, comprising the DNA construct of claim 12.

25 23. The P. pastoris cell of claim 22, wherein said cell is selected from the group consisting of strains G+IGF201S1, G+IGF816S1, G+IGF816S2, M+IGF816S1 and C+IGF816S1.

24. A P. pastoris cell, comprising the DNA construct of claim 13.

30 25. The P. pastoris cell of claim 24, wherein said cell is selected from strains G+IGF206S2, G+GF816S9, G+IGF816S11, G+GF816S9 and G+IGF816S11 G+IMB202S2 G+IMB204S14, G+IMB206S1, G+IMB206S2, G+IMB206S3, G-IMB206S1, G+IGF816S9, G+IGF816S11, M+IGF816S4 and M+IMB206S1.

35 26. The P. pastoris cell of claim 24, wherein said

-89-

cell is selected from the group consisting of strains G+IGF206S2, G-IMB206S3, G+IMB206S1, G+IMB202S2, and G+IMB204S14.

27. A culture of viable methylotrophic yeast cells,
5 comprising yeast cells of claim 18.

28. A culture of viable P. pastoris cells,
comprising yeast cells of claim 22.

29. A culture of viable P. pastoris cells,
comprising a single strain of yeast cells of claim 23.

10 30. A culture of viable P. pastoris cells,
comprising yeast cells of claim 24.

31. A culture of viable P. pastoris cells,
comprising a single strain of yeast cells of claim 25.

32. A process for producing insulin-like growth
15 factor-1 (IGF-1) peptides, comprising culturing the cells
of claim 18 under conditions whereby said cells express
and secrete mature IGF-1 peptide into the culture medium.

33. A process of claim 32, wherein said
methylotrophic yeast is a strain of Pichia pastoris.

20 34. The process of claim 32, wherein said cells are
cultured in a medium containing methanol as a carbon
source.

35. The process of claim 32, wherein said cells
have the Mut⁺ phenotype.

25 36. The process of claim 32, wherein said cells
have the Mut⁻ phenotype.

37. The process of claim 32, wherein the cells are
proteolytically intact and the pH of the medium is
between about 2 and about 4.

30 38. The process of claim 37, wherein the pH is
less than about 3.

39. The process of claim 32, wherein said cells
are protease deficient and the pH of the medium is
between about 2 and 5.

35 40. A process for producing insulin-like growth

-90-

factor-1 (IGF-1) peptides, comprising culturing the cells of claim 21 under conditions whereby said cells express and secrete mature IGF-1 peptide into the culture medium.

41. The process of claim 40, wherein said
5 methylotrophic yeast is a strain of *Pichia pastoris*.

42. The process of claim 40, wherein said cells are grown in a medium containing methanol as a carbon source.

43. The process of claim 40, wherein said cells have the Mut⁺ phenotype.

10 44. The process of claim 40, wherein said cells have the Mut⁻ phenotype.

45. The process of claim 40, wherein the cells are proteolytically intact and the pH of the medium is between about 2 and about 4.

15 46. The process of claim 40, wherein the pH is less than about 3.

47. The process of claim 40, wherein said cells are protease deficient and the pH of the medium is between about 2 and 5.

20 48. The strain of claim 20, wherein said strain is protease deficient and wherein said deficiency does not affect at least one protease that recognizes said processing site.

49. The strain of claim 48, wherein said deficiency
25 results in an absence or reduction in the concentration of one or more proteinases selected from the group consisting of proteinase A, carboxypeptidase Y, and proteinase B.

50. The strain of claim 49, which is M+IMB206S1,
30 M+IGF816S1, M+IGF816S4, or C+IGF816S1.

V. ☐ OBSERVATIONS WHERE CERTAIN CLAIMS WERE FOUND UNSEARCHABLE¹

This international search report has not been established in respect of certain claims under Article 17(2) (a) for the following reasons:

1. ☐ Claim numbers _____, because they relate to subject matter ¹² not required to be searched by this Authority, namely:

2. ☐ Claim numbers _____, because they relate to parts of the international application that do not comply with the prescribed requirements to such an extent that no meaningful international search can be carried out ¹³, specifically:

3. ☐ Claim numbers _____, because they are dependent claims not drafted in accordance with the second and third sentences of PCT Rule 6.4(a).

VI. ☐ OBSERVATIONS WHERE UNITY OF INVENTION IS LACKING¹

This International Searching Authority found multiple inventions in this international application as follows:

1. ☐ As all required additional search fees were timely paid by the applicant, this international search report covers all searchable claims of the international application.

2. ☐ As only some of the required additional search fees were timely paid by the applicant, this international search report covers only those claims of the international application for which fees were paid, specifically claims:

3. ☐ No required additional search fees were timely paid by the applicant. Consequently, this international search report is restricted to the invention first mentioned in the claims; it is covered by claim numbers:

4. ☐ As all searchable claims could be searched without effort justifying an additional fee, the International Searching Authority did not invite payment of any additional fee.

Remark on Protest

☐ The additional search fees were accompanied by applicant's protest.

☐ No protest accompanied the payment of additional search fees.
